OXYGEN

For the cutting and welding of metals

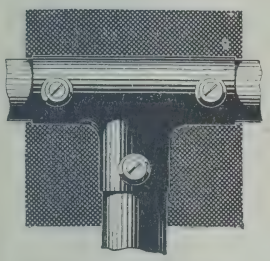
If you are not yet making use of Oxygen for Cutting, and the Oxy-Acetylene Welding Process, or wish to hear of the latest improvements in both, write to the British Oxygen Company.

THE BRITISH OXYGEN COMPANY, the Founders of the Oxygen Industry, have highly equipped and up-to-date factories in all the important British Industrial Centres, capable of producing over

2,000,000 CUBIC FT. OF OXYGEN DAILY.

The Company are the foremost manufacturers in Great Britain of—

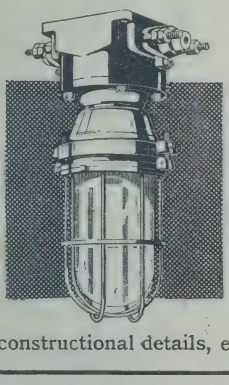
Oxygen Metal-Cutting Apparatus, Oxy-acetylene, Oxy-hydrogen and Oxy-coal Gas Welding Blowpipes, High Pressure Gas Regulators, etc.



For catalogues and full particulars apply to any of the Company's Works:

Angel Road, Upper Edmonton, N.18. North Wembley, Middlesex. Tunnel Avenue, East Greenwich. Shields Road, Walker Gate, Newcastle. Lower Walsall St., Wolverhampton. Terry Road, Coventry. Great Marlborough St., Manchester Rosehill, Polmadie, Glasgow. East Moors, Cardiff. Savile St., Sheffield. Bromborough Port, Nr. Birkenhead. Lodge Road, Hockley, Birmingham. Knowsley Road, Bootle, Nr. Liverpool. Saville Green, York Road, Leeds.

THE BRITISH OXYGEN CO LTD



BRANCHES IN ALL THE PRINCIPAL INDUSTRIAL CENTRES.

Angel Road, Upper Edmonton, LONDON, N.18.

SIMPLEX

THE Simplex 'Terra-grip' System—the new Continuity System of Conduit Wiring—has been introduced to provide a cheaper means of ample and permanent electrical conductivity in light gauge unscrewed conduit installations than is possible with heavier grip systems; and, in fact, is such that an installation erected on this system costs but little more than one on the ordinary socket joint principle. Constructional details and evidence of its remarkable efficiency, together with full range of priced fittings, are contained in List No. 893. Copies on application.

THE Simplex Colliery Lighting System, designed, manufactured, and now being supplied by Simplex Conduits Ltd., comprises a complete range of carefully designed water-tight Junction Boxes fitted with 'easy wiring' interiors and having clamping and bonding glands for use in conjunction with S.W.A. twin V.I.R. cables up to 7/.036.

The excellency of the design and the interchangeability of the component parts (which are reduced to a minimum), has strongly impressed all Colliery Managers, Engineers, and Store-keepers to whom the System has been introduced. For full constructional details, etc., write for Booklet No. 861.

Turbine Pumps

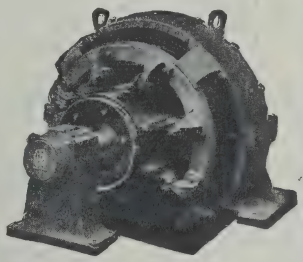
For all Duties. We manufacture Colliery and Mining Pumps, Sinking Pumps, Water Supply Pumps, Irrigating and Circulating Pumps, Boiler Feed Pumps and Well Pumps—ANY CAPACITY—ANY HEAD—ANY SPEED. The Design is correct, the best workmanship is employed, and the highest quality material used.

Our engineers are at your service to advise on all pumping matters. Advise us of your requirements.

Mather

PARK WORKS,
MANCHESTER.

Textile Machinery



There is no want in connection with the equipment of Bleaching, Printing, Dyeing, and Finishing Works which we cannot fulfil. Write us your requirements. We shall be pleased to submit estimates and specifications.

Some Specialities:

Gas Singeing Machines, Spray Damping Machines, High-Speed Stentering Machines, High-Speed Beetling Machines, Calenders for all purposes, Open Soaping Ranges, Mather Kiers, Mercerising Ranges, Printing Machines, Filter Presses, Dyeing Machines for Cops, Cheeses, Raw Cotton, etc.

Electrical Machinery

We specialise in the manufacture of high-grade electrical machinery, and undertake the complete electrical equipment of Mines, Collieries, Ironworks, Textile Factories, Bleach Print and Dye Works, Paper Mills, Central Stations, &c. &c. Our Electrical Plant, because of its sound engineering, high-class materials and expert workmanship, has gained for us an enviable reputation for sterling quality.

& Platt, LTD.

14 GREAT SMITH STREET,
LONDON, S.W. 1.

"*Simplex*"
Fire Extincteurs

"Simplex" Extincteurs are unequalled as first-aid fire appliances. They are strongly constructed, easy to handle and operate, and most efficient in fire extinguishing qualities. The chemical used does not deteriorate—it is as efficient after ten years as on the day the extincteur was first charged.

Supplied to the British Government in huge quantities.

GOOD-BYE BROKEN TOOLS!

Chisels, Sates, Pneumatic and Shock Tools—how many do YOU break every month?

"PAX NON-BREAK" STEEL

(Oil-Hardening) is our newest product and we're proud of it. Greater cutting efficiency, longer life, effective on all materials —even with a steam hammer drive. *YOU CAN'T BREAK IT!*

Dustless (Concrete) Floors that never wear out

If you are building a new Factory take the precaution of having the floors laid with a mixture of cement and 'Ferrolithic.' This adds but little to the cost and is more than justified by reason of the fact that subsequent repairs are eliminated. Floors laid with

Ferrolithic

CONCRETE HARDENER FOR FLOORS

never wear into ruts like ordinary concrete floors. They are as hard as iron, and are wear, oil, and water proof; the most durable floors known and quite dustless —an important factor where machinery is installed. A 'Ferrolithic' Floor will last the life of the building.

Complete specifications are contained in our booklet. A postcard will bring it to your desk by return.

1922

THE PAXMAN Positive Valve Gear engines are suitable for boiler pressures up to 200 lb. per square inch, with a total steam temperature up to 600 degrees Fahr.

The economy of the steam consumption of these engines is remarkable, it being possible to obtain one-horse power for every 9½ to 10½ lb. of superheated steam.

With an installation comprising our 'Economic' type of boiler and Positive Valve Gear engine combined, we are able to guarantee consumptions of 1·1 to 1·2 lb. of coal per I.H.P. per hour under suitable conditions.

PREFACE TO FIRST EDITION (1894).

The importance and value of such a work as The Engineer's Year-Book need hardly be insisted on. Perhaps there is no professional man who *needs* a Year-Book more than the Engineer of the present day, seeing that his duties are so multifarious and the requirements of his position so constantly varying. Yet, while other professions have their Year-Books, until now none has been provided for the Engineer; it is confidently believed that the present volume will meet a want that is constantly experienced by Practical Men in every branch of Engineering.

The aim of the compiler has been to produce a work which, being carefully brought up to date, shall take its place as the standard Book of Reference in the profession, and include only such Modern Formulæ, Rules, Tables, and Data as are required by the Engineer from day to day in the practical work of his calling, including Civil, Mechanical, Marine, Electrical, and Mine Engineering. The work is accordingly divided into Thirty-one Sections, each Section forming practically a complete treatise on its particular subject, and the whole embracing the present practice of Engineering.

The great advances made in Science, as applied to Engineering, during the last quarter of a century have fixed immutably many new principles, laws, and practical data. These, as well as the like particulars of older practice, have been carefully compiled from the best authorities, and find their place in The Engineer's Year-Book, whilst a large amount of original matter, presented in a handy and concise form, is also included in the volume.

In the work of compilation, most valuable assistance has been rendered by numerous practising Engineers, including those of the principal English Railway Companies, and of the Queensland Government, as well as by

502750

Girder Manufacturers, Boiler and Engine Makers, and many other persons of experience. Every available work has been searched through and consulted for information, but in making use of particulars so obtained the compiler has been at pains to trace the matter to its original source, so as to determine its authoritative value, and in every case where it appeared necessary he has redrawn existing figures and verified current formulæ, so that clearness and accuracy might be ensured.

Obviously a work of this nature, to fulfil its purpose of being kept up to date, will require periodical revision, and it is accordingly intended to REISSUE IT FROM YEAR TO YEAR. The facilities thus afforded for thorough revision throughout the volume will make it practicable to *insert every year new matter of importance in any Section*, and render the book at all times a safe and reliable DAILY REFERENCE BOOK for the PRACTICAL ENGINEER.

Kindly criticism and help towards making the work as complete and as useful as possible are earnestly invited, and any suggestions, addressed to the care of the Publishers, with this object, will be gladly received, and, as far as possible, acted upon.

I have to thank Mr. H. HARTNELL, Technical Officer of the Engineer-in-Chief's Office, for great assistance rendered in the work of compilation.

Finally, I think more than a word of thanks is due to the printers, Messrs. SPOTTISWOODE & Co., for the able manner in which they have executed the difficult task of concisely and clearly arranging the letter-press.

H. R. KEMPE.

ENGINEER-IN-CHIEF'S OFFICE,
GENERAL POST OFFICE, LONDON:
January 1894.

PREFACE TO 1922 EDITION.

In the preparation of the present issue of The Engineer's Year-Book, the numerous Associate-Editors and Contributors (who have been selected for their expert knowledge of the particular branches with which they deal) have subjected their respective sections to a thorough revision, making important alterations and additions in order that Modern Engineering practice may be the standard throughout the volume. Not only have new sections been introduced and old matter rearranged, but much information which advances in practice have rendered obsolete, has been excised, so that the actual number of new pages is greatly in excess of that indicated by the numerical pagination total, which has now reached nearly 2650, an increase of over 2000 upon that of the first issue.

Special prominence should be given to the fact that the important section relating to Steam Power has been entirely recast and largely rewritten by Dr. T. B. Morley, M.I.Mech.E.; whilst among other sections which have also been rewritten or largely added to for the present issue, are the following, the authorities responsible being quoted in brackets :—

'Electrical Engineering'; 'Electric Traction' (A. H. Allen, M.I.E.E.).

'Acetylene' (Charles Bingham).

'Internal Combustion Engines' (A. Vincent Clarke, A.M.Inst.C.E., M.I.Mech.E., A.M.I.E.E.).

'Harbours,' 'Docks,' and 'Navigable Waterways' (Dr. Brysson Cunningham, F.R.S.E., M.Inst.C.E.).

'Steam Turbines' (H. L. Guy, A.M.Inst.C.E.).

'Pulverised Coal' (L. C. Harvey).

'Naval Architecture' and 'Marine Engineering' (Professor P. A. Hillhouse, D.Sc., M.I.N.A., and James Thomson, M.I.N.A.).

'Metering of Water, Air, Gas, and Steam' (J. L. Hodgson, B.Sc., A.M.I.C.E.).

'Locomotives' and 'Railway Rolling Stock' (H. Holcroft, M.I.Loco.E.).

'Cranes and Lifting Appliances' (J. H. Huntley, M.I.E.S.).

'Aircraft' (Major D. H. KENNEDY, F.R.Aë.S., R.A.F.).
'Coal and Metalliferous Mining' and 'Mine Valuation' (Professor HENRY LOUIS, D.Sc., M.Inst.C.E.).
'Gas and Gasworks Practice' (ALWYNE MEADE, A.M.Inst.C.E.).
'Fuels: Solid, Liquid, and Gaseous' (HAROLD MOORE, M.Sc., F.C.S.).
'Cost Data' (JOHN T. REA).
'Oxy-Acetylene and Electric Welding and Cutting' (D. RICHARDSON, Wh.Ex., A.M.I.M.E.).
'Mortars,' 'Concretes,' 'Cements' and 'Plasters' (ALFRED B. SEARLE).
'Machine Tools,' 'Workshop Practice,' 'Power Transmission,' and 'Bearings' (DEMPSTER SMITH, M.B.E., M.Sc., M.I.Mech.E.).

The official permission given by the several Institutions of Civil, Mechanical, and Electrical Engineers, and of Naval Architects, for extracts to be published from their proceedings (a privilege which, it is needless to say, is of exceptional value) has been fully taken advantage of.

As the object of the work is to combine scientific with commercial information, the introduction of matter of an advertising character (but which has been inserted in harmony with the general scheme of the book) has been inevitable. Great care, however, has been exercised to ensure that such information shall be of the highest class, and the sole responsibility for its insertion rests on the Editor-in-Chief.

Invaluable assistance in the revision and preparation of the work has been rendered by Mr. FRANCIS C. SMITH, also by Mr. W. HANNEFORD SMITH, who for the past fourteen years has most ably discharged the duties of Assistant Editor-in-Chief. In this respect it is not too much to claim that the engineering profession owes to Messrs. SMITH a debt of gratitude, for it is largely due to their initiative and zealous help that the work has attained to its present standard of excellence and comprehensiveness.

Thanks are also due to numerous other contributors for useful matter supplied, and for practical suggestions.

Friendly criticism calculated to increase the utility of the work will be welcomed at all times and as far as possible acted upon.

H. R. KEMPE.

ENGINEERING STANDARDS.

By special permission of the British Engineering Standards Association the Editors have been enabled to include, in abstract form, the following Specifications and Recommendations of the Association :—

No. 1. 1920. Rolled Sections for Structural Purposes.
„ 2 1903. *Tramway Rails and Fishplates.
„ 6. 1904. Rolled Sections for Structural Purposes.
„ 7. 1919. Copper Conductors, Insulated Annealed for Electric Power and Light.
„ 8. 1904. Tubular Tramway Poles.
„ 9. 1909. *Bull-head Railway Rails.
„ 10. 1904. Pipe Flanges.
„ 11. 1909. *Flat-bottom Railway Rails.
„ 12. 1920. Portland Cement.
„ 13. 1910. Structural Steel for Shipbuilding.
„ 15. 1912. Structural Steel for Bridges and General Building Construction.
„ 21. 1909. Pipe Threads.
„ 23. 1905. Trolley Groove and Wire.
„ 24. 1911–1921. Material used in the Construction of Railway Rolling Stock, Parts I. to VI.
„ 27. 1906. Limit Gauges for Running Fits.
„ 28. 1908. Nuts, Bolt Heads, and Spanners.
„ 31. 1910. Steel Conduits for Electrical Wiring.
„ 37 1919. Electricity Meters.
„ 40. 1908. Cast-iron Spigot and Socket Low-pressure Heating Pipes.
„ 41. 1908. Cast-iron Spigot and Socket Flue or Smoke Pipes.
„ 43. 1909. Charcoal Iron Lapwelded Boiler Tubes.
„ 53. 1913. Cold Drawn Weldless Steel Tubes for Locomotive Boilers.
„ 57. 1920. Heads for British Association Screws.
„ 65. 1914. Salt Glazed Ware Pipes.
„ 72. 1917. Electrical Machinery.
„ 78. 1917. Cast-iron Pipes for Water, Gas, and Sewage.
„ 84. 1918. Fine Screw Threads and their Tolerances. Superseding parts of Nos. 20 and 38.
„ 91. 1921. Electric Cable Soldering Sockets.
„ 102. 1921. Tramway Axles.
„ 109. 1921. Switches.
„ 110. 1921. Circuit Breakers.
„ 115. 1921. Metallic Resistance Materials for Electrical Purposes.
„ 132. 1 20. Steam Turbines for Electrical Plant.
„ 133. 1921. Vacuum Tungsten Filament Electric Lamps.
„ 135. 1921. Benzol for Motor Fuel.
„ 139. 1921. Red Fir Wood Poles for Telegraph and Telephone Lines.
„ 144. 1921. Creosote for the Preservation of Timber.

C.L. (M) 7270—1919. British Standard Whitworth Screw Threads.

Complete (official) copies of the Association's Reports may be obtained from the Secretary, Charles Le Maistre, A.M.Inst.C.E., 28 Victoria Street, Westminster, S.W. 1, or Messrs. Crosby Lockwood & Son, each at 1s. net.

* Revised editions of these three Specifications are approaching completion and are expected to be published in the early future.

Furniture's part in Office Organisation

Apart from the material conveniences well-designed furniture affords in the office, it creates an atmosphere which induces better work and which cannot fail to affect, to your advantage, those with whom you seek business.

THE PAST YEAR'S PROGRESS.

(*Abstracted from the Engineering Section of 'The Times' Trade Supplement, January,* 1922.)

SHIPBUILDING AND MARINE ENGINEERING.

Costs of construction are now considerably lower than they were six months ago, but they are still so much higher than the market price of new tonnage that no contracts can be obtained for ordinary trading steamers. There are, at the moment, a considerable number of cargo steamers of about 8,000 tons deadweight on the stocks, the contract price of which, or the ultimate anticipated price after all costs have been paid, will be about £300,000. Of these, any one can be obtained for £150,000, and in some cases the owners would be quite willing to accept £100,000. No vessels are being ordered now at anything like even the last-named figure. Somewhere between £10 and £15 per ton deadweight is the maximum named when vessels of the type are mentioned, and no business is being done at that price.

According to the statistics compiled by *The Glasgow Herald*, there were launched, during the year, some 2,402 vessels, of 5,189,493 tons and 4,552,643 h.p., which represented a decrease, as compared with the previous year, of 872 vessels, 1,757,691 tons, and 2,185,237 h.p. But of this decrease 406 vessels, 1,439,332 tons, and 1,686,431 h.p. were in the United States alone, while in the United Kingdom the falling off amounted to 365 vessels, of only 544,656 tons and 381,318 h.p. All the British tonnage consisted of ships of thoroughly efficient types.

An output of 804 vessels of 1,596,272 tons and 1,318,788 h.p. is probably only about half of what United Kingdom shipyards and engine-shops are capable. Nearly 1,600,000 tons of new shipping were launched, containing a much larger proportion of geared turbine cargo steamers, oil tankers, and motor-propelled ships than the output of any previous year; also there were launched a small number of liners of the most efficient kind, and the most exactly adapted for their respective services, ever constructed.

There were three outstanding types of vessels built during 1921—geared turbine steamers, oil-tankers, and motor ships. The majority of the oil-tankers were designed for propulsion by geared turbines, so that the two classes overlap to a certain extent. The new adaptation of the steam turbine has been found to be suitable for vessels of practically all sizes and speeds. The internal-combustion engine has been proved thoroughly successful in the propulsion of vessels of certain sizes and speeds, and none of those companies which has adopted it seems in the least inclined to revert to steam; instead, some of the Continental firms who had fleets

composed partly of steamers and partly of motor ships have given up steamers altogether and propose in future to put their dependence wholly in motor-propelled vessels. It is the case, however, that the range of service of the marine internal-combustion engine is still somewhat restricted, that motor ships cannot be shifted about from one trade to another so freely as steamers, that this type of machinery is still being made only in a limited number of powers, and that it is not yet so free from the danger of breakdown as is the steam engine. Notwithstanding these disadvantages the motor ship is making very notable progress. The 1921 output of vessels of the type was more than double that of any previous year. The ships completed aggregated 333,475 tons dead weight, while, in addition, vessels representing 239,850 tons were launched and were being fitted out when the year closed. In the vessels completed, Diesel engines of 126,500 h.p. were installed, while for those fitting out, engines of nearly 100,000 h.p. had been, or were being, constructed. During the year the Burmeister and Wain engine was fitted to a preponderating number of British-built vessels—constructed almost wholly on the Clyde ; but there were also completed in the United Kingdom large vessels having Werkspoor, Sulzer, Camellaird-Fullagar, North British Diesel, and Beardmore-Tosi engines respectively, as well as several for propulsion by Vickers' engines.

Two firms are said to have abandoned the double-reduction geared turbine and to be going back to reciprocating engines for their new construction, owing to trouble not only with the gears but also with the turbines.

Messrs. Robey, of Lincoln, are understood to be completing a three-cylinder inverted vertical marine unit of the uniflow type, and German makers have adopted drop-valve engines to some extent. It appears probable that progress will be in the direction of modifying the standardised form of reciprocating engine in such a way as to give indicator cards more nearly approaching the theoretical best than can be obtained with the ordinary slide valve and its gear. The success of cam-operated valves in internal-combustion engines is overcoming the prejudice of marine steam engineers against valves and gear functioning in a similar manner, and it seems likely that land practice in this respect will be followed to a greater extent in marine work.

There has been little opportunity to ascertain the reliability and longevity of the highly loaded gears which have been fitted in some ships, such as the Anchor Liner *Cameronia*. In the discussion on Messrs. Walker and Cook's paper at the spring meetings of the Institution of Naval Architects, it was stated that this ship's gears had given every satisfaction so far, and it appears that this early promise has been substantiated in subsequent running. It was emphasised also that such a result can be expected only with first-class material and workmanship, and with skilled attention on service, and this view is confirmed by unfortunate experiences with other ships in which the equipment was not of so high an order of excellence.

The floating frame does not yet find favour in this country, though the necessity for preserving the alignment irrespective of movement of the

ships' seatings is recognised to be of vital importance. In this connection reference may be made to a patent (No. 168,926) of the Metropolitan-Vickers Company for diagonally bracing the seating external to the gearing; it is understood that this scheme has been adopted in a Dutch steamer. The so-called 'nodal' drive has been installed in the *Vandyck* (built for Messrs. Lamport and Holt by Messrs. Workman, Clark and Co.), and also partially in the Canadian Pacific Railway's *Empress of Canada* at Fairfield. A further development is the substitution of spur for helical gears, with teeth cut and ground according to the system devised by the Maag Gear Company, of Zurich. Gearing of this kind has been fitted in the French steamer *Thorium* and the Danish vessel *Niobe*, but the tooth loadings quoted in a paper on the subject read by Engineer Lieutenant-Commander Le Mesurier before the North-East Coast Institution of Engineers and Shipbuilders are very high for spur gears, and it is doubtful whether the plan will commend itself to British engineers.

Interest in stainless steel as a material for turbine blades was renewed by the exhibition at Sheffield of a turbine in which blades of that material had been run for a prolonged period with satisfactory results, and a great extension of its use appears probable.

Among the more notable ships of the year were the *Cameronia*, *Scythia*, *Montcalm*, and *Empress of Canada*, all twin-screw vessels having double-reduction gearing and turbine machinery of the impulse type. In the first three there are three turbines to each screw, but in the last the high-pressure and low-pressure turbines are coupled in tandem and drive the out-board first-reduction pinions, while the in-board pinions are driven by the first and second intermediate pressure turbines similarly coupled. In the *Moreton Bay* and *Largs Bay*, compound turbines of the Parsons variety are fitted. An unusual arrangement was adopted in the *Giulio Cesare*, in which two high-pressure units drive two shafts through single-reduction gears, and two low-pressure units another pair of shafts though similar but separate gears. The greatest departure from standard practice was in the *Pacific*, the machinery of which consists of a single Ljungström oppositely rotating unit driving double-reduction gearing through a reversing clutch of the plate type. So far the equipment has justified itself, as the ship has completed two round voyages to the Far East and back on a consumption of 1 lb. of coal per shaft horse-power hour—a figure so far unapproached by any other system of steam propulsion. After some 60,000 miles of sea service the machinery, including the clutch, was said to be in perfect condition, which is remarkable for an installation of 2,000 h.p. transmitted through a reversing gear of this description. The credit for this performance, which seems to be largely overlooked in this country, is due to the Swedish Ljungström Company.

The Scotch boiler still holds its own in merchant ships to the almost complete exclusion of the water-tube type, except for cross-Channel craft. Some of the German liners handed over to this country are, however, fitted with a three-drum type of water-tube boiler, and in the case of the *Majestic* it is estimated that some 2,000 tons of material, exclusive of water, have been saved by the substitution of Yarrow-type for cylindrical boilers.

Oil-firing continues to grow in popularity, and the success of the *Aquitania* since she was converted from coal has been so great that the Cunard Company are fitting the *Mauretania* and *Berengaria* in like fashion; the *Empress of France* is also to be converted.

Superheated steam is being more generally applied, most owners being now convinced that the cost of installing the necessary plant is repaid by the economy gained.

The tendency to instal rotary in place of reciprocating auxiliaries, which was noticeable in 1920, shows a further increase, and the provision of turbine-driven extraction pumps, combined with steam ejectors for air-pumping plant, promises to become standard for turbine work. Messrs. Weir are also adopting steam ejectors in conjunction with their Dual-type air pumps, and are eliminating a source of loss by omitting the cooler usually fitted.

There has been a considerable advance in the electric drive, particularly in the United States. Several mercantile vessels of the steam-electric class have been completed and are in service, including the *Invincible*, *Cuba*, *Eclipse*, and *Independence*, and very favourable reports have been received of the *San Benito*, recently put in service by Messrs. Workman, Clark and Company, the machinery of which is similar. The Japanese have completed a ship, the *Biyo Maru*, fitted with Ljungström turbo-electric machinery on the model of the *Wulsty Castle*, and it is reported that the Japanese Government has ordered in the United States a large tank steamer to be equipped with electric drive. The trial results obtained with the U.S. battleships appear to have fulfilled expectations, and four coastguard vessels are in hand.

INTERNAL COMBUSTION ENGINES.

Most of the manufacturers of stationary oil engines who have built up their reputation during the past fifteen or twenty years with the low-compression horizontal class of motor have now adopted some form of high-compression engine, which in several cases, as, for instance, the Ruston Hornsby sets, is built with a power of 200 b.h.p. per cylinder. The compression pressure varies from 300 lb. to 425 lb. per sq. in., the former representing the figure employed in the Crossley type and the latter that in the Ruston Hornsby engine. In all cases, mechanical injection of fuel is used. The difference in thermal efficiency with the varying types does not appear to be considerable, and in the larger engines built in 1921 a brake thermal efficiency of 35 per cent. was attained at the working load, corresponding with a fuel consumption of about 0·42 lb. per b.h.p. hour when running on Diesel fuel of 0·91 specific gravity. Heavier grades of fuel oil have been satisfactorily used, and tar oil has been adopted in certain cases. With the latter it is usual to fit a second pump on the engine to supply the oil for pilot ignition before the main fuel charge enters the cylinder. The amount of pilot oil required has been found to be in the neighbourhood of 6 per cent. of the total fuel supplied when the engine is running at its full load, but it is to be noted that this quantity does not diminish with the load.

This fuel consumption is about equal to that attained on corresponding

Diesel motors and is lower than with Semi-Diesel engines, and as the high-compression horizontal oil engine would appear to be cheaper to build than either of the other two, it is likely to make considerable headway for stationary purposes in the course of the next few years. It is satisfactory to record that this development is due almost wholly to British engineers, as the type has not yet made its appearance on a large scale either in America or on the Continent.

Comparatively few innovations have been made to existing designs of Diesel engines, but there is a tendency towards higher speed of rotation, and in some cases engines have been built up to 400 and 500 b.h.p. operating at 375 r.p.m. Important experiments have been carried out by two of the leading Diesel engine manufacturing firms, one in this country and one on the Continent, with a new system of solid injection of fuel at a much lower compression than that now used, which is 4,000 lb. per sq. in. in the Vickers engine, and 9,000 lb. in the Doxford motor. The experiments with this new method have proved successful, and it is anticipated that stationary high-speed engines fitted with the new device will be standardised during the present year.

Among the numerous large marine Diesel engines that were put to practical test for the first time in 1921 greatest interest attaches to those of the opposed piston design built respectively by Messrs. Cammell Laird and Messrs. Doxford. The standard 3,000 i.h.p. Doxford engine has the highest cylinder output of any Diesel motor yet manufactured commercially, this being 750 i.h.p., or about 650 b.h.p. at the low speed of 77 r.p.m. The engine is, further, remarkable for the adoption of solid injection of fuel and the employment of the extremely moderate compression pressure of 300 lb. per sq. in. The first examples of the four-cycle engines of the North British Diesel Engine Works were completed, and, although embodying no radical departures from orthodox practice, were noteworthy as being wholly of British design. A new Burmeister and Wain long-stroke Diesel motor was brought out with a stroke-bore ratio exceeding two to one and running at 85 r.p.m; the object of this is to produce a type specially suited for installation in single-screw ships where low propeller speed is desirable.

Substantial progress was made in improving the design of the Semi-Diesel engine during the past year. Two entirely new engines were brought out in this country, one by Marshall, Sons, and Co., in both the horizontal and the vertical forms, and the other by J. S. White and Co., of Cowes, embodying a new system of supercharging which, it is believed, will tend to higher efficiency.

Progress was made with the Still combined steam and oil engine, and the first large engine of a commercial type was completed and thoroughly tested by Scott's Shipbuilding Company. The results achieved in the test appear to bear out some of the claims made for the engine. The fuel consumption, allowing for the power required for operating all auxiliaries, such as the scavenging, lubricating oil, circulating water and fuel oil pumps, was found to be 0·375 lb. per b.h.p. hour at full load, corresponding with a brake thermal efficiency of 37·7 per cent.

Little that is new has to be recorded in connection with gas engines in 1921. A good deal of work was carried out on the Smith gas producer. It has been adapted mainly for driving commercial vehicles and motor craft and is standardised in sizes suitable for running engines from 35 to 100 h.p.

COAL MINING.

It is estimated that 45 per cent. of the coal produced at the collieries in the United Kingdom consists of coal under $1\frac{1}{2}$ in. to $1\frac{3}{4}$ in. in size—that is to say, putting the annual output, in normal times, at 260,000,000 tons, 117,000,000 tons consist of what is called 'small' or slack coal. The quantity of small coal at present washed is estimated at about 15,000,000 tons, and 18,000,000 tons of small are consumed at the collieries. Deducting these quantities, a balance of 84,000,000 is left, much of which would be improved by washing, for from 1,000 analytical tests made of this coal it contains, on the average, not less than 12 per cent. of ash, which by washing could be reduced to 5 per cent. The results obtained in improved calorific value, higher selling price, and saving in transport seem to warrant the more extensive cleaning of coal in the United Kingdom.

A type of coal-washing plant which has recently been introduced into Great Britain from Belgium for washing slack coal, and which is likely to prove very successful owing to its efficiency and the simplicity of its construction, is the 'Rheolaveur.' The medium employed for separating the coal from the dirt is an upward current of water which passes through slots placed at intervals in a channel or trough along which the coal is borne by a current of water. The mixture of the coal and dirt stratifies in the trough; the lighter (coal) particles do not pass through the slots, but the heavier (dirt) particles do. A comparatively weak upward current of water suffices to ensure that only the dirt, usually in the form of shale, passes through the slots and is rejected. The apparatus is so constructed that the coal can be automatically returned to the coal bunker and re-washed if necessary. It is stated that all the labour needed for the plant is one man (a mechanic) in charge and two youths. In one case where there are two washeries, each of a capacity of 70 tons per hour, the circulation water required is not more than 77,000 gallons per hour, and the same water can be used over and over again. The power required to work the washery is 35 h.p.

Several installations of fine coal recovery plants using the froth flotation process are now in course of erection in the United Kingdom—namely, at Oughterside Collieries in Cumberland, at Skinningrove Iron and Steel Works in Yorkshire, at the Team Valley By-Product Works near Gateshead, and at Ashington in Northumberland. The pioneer plant in Aberaman continued in operation throughout the year.

The recovery process appears to be peculiarly suitable where a super-clean product for the manufacture of metallurgical coke is desired, but where a second-class product is required, for, say, boiler firing, it can also be obtained. It has been demonstrated that the process is capable of converting a semi-coking into a coking coal by separating the portion which

has coking properties from that which has none, rendering the former available for coking and the latter for boiler firing or any other purpose.

It has been shown at Aberaman that 98·8 per cent. of the true coal present is recoverable, the cleaned product carrying only 1·2 per cent. of free dirt. The physical strength of the coke made from coal cleaned by the froth flotation process proves to be greater than that of ordinary coke. In one example the strength of the coke to resist crushing was 2,076 lbs. per sq. in., as against 1,500 lbs., the average strength previously obtained from the same coke, but uncleaned.

A development is the discovery by Minerals Separation, Ltd., of a new method of briquetting. Experiments on a large scale have been carried out at the works of the Powell Duffryn Steam Coal Company, South Wales. The process consists in adding a suitable binding medium, less in quantity than that employed in ordinary briquetting, to the original product, when agglomeration takes place so readily that apparently only the application of pressure is required to produce a satisfactory briquette; that is to say, the briquettes are produced directly from the wet fine coal recovered by the flotation process. The ordinary method of making briquettes is to dry the crushed coal, mechanically mix the coal and binding material, and subject the mixture to the briquetting press.

Since the issue of the report on mechanical coal cutting by the North of England Institute of Mechanical Engineers in 1905, the increase in point of number of collieries at which mechanical cutters are in use has been over 128 per cent., and in the number of machines in use over 346 per cent., while the total output of minerals obtained by mechanical machines increased from 4·0 per cent. in 1906 to 12·8 per cent. in 1920. There is a limit to the extent to which mechanical cutters can be applied profitably, and this limit is determinable by the natural conditions of coal in the seam itself and the character of the roof and floor of the seam. There is, however, as yet no hint that this limit has been reached.

The Powell Duffryn Company are putting down a central compressed air generating plant in their new Bargoed power-house with the intention of distributing compressed air at 85 lbs. pressure by a system of welded steel pipes varying in diameter from 28 ins. to 12 ins., and linking together their various collieries, which are eight or ten miles apart. The compressed air will be produced by three 40,000 cu. ft. per minute steam turbine-driven rotary compressors, each turbine being upwards of 7,000 h.p. capacity. The pressure drop is calculated not to exceed 10 per cent. at the pit top when all the collieries are taking their maximum load. A number of expansion joints are provided in the pipe line.

FUEL UTILISATION.

It cannot be said that the past year was marked by any outstanding developments that can be recorded as distinct advances in the various branches of fuel technology.

Some considerable extension was noticeable in the use of coke as a fuel

for motor transport, and one well-known firm of steam wagon manufacturers who have designed a special boiler for use with this fuel stated that, with a load of 6 tons, a mileage of 15 per cwt. of coke may be regarded as an average consumption. With coke at 45*s.* per ton, this would amount to 2*d.* per vehicle mile. Mr. Thomas Clarkson expressed the opinion that from the standpoint of running costs there is little to choose between lorries which raise steam with coke and those which convert the same fuel into producer gas. The conclusions he arrived at were that petrol at 2*s.* 4*d.* per gallon costs 4*d.* per vehicle mile with a 3-ton lorry, that steam raised by means of coke costs 1*d.* per vehicle mile, and that producer gas costs about two-thirds of a penny. The additional expense incurred, however, in the maintenance of the producer and engine, turned the scale in favour of utilising the coke for steam.

It should be noted that a plant for firing a Stirling boiler with powdered coal on the Holbeck system was put down at the electricity works of the Hammersmith Corporation. In this instance the coal is made as required in a self-contained turbo-pulveriser, and the system operates under a slight vacuum, so that there should be no chance of coal dust escaping into the atmosphere.

The Distillers' Company has been conducting experimental work abroad on power alcohol and, it was said, is in a position to supply seven million gallons a year from its own distilleries. The product (known as D.C.L. fuel) consists of a mixture of 50 per cent. alcohol, 25 per cent. benzol, and 25 per cent. paraffin. Sir Charles Bedford announced the completion of tests designed to show that alcohol may be produced commercially in Burma as a product of the paper industry which it is proposed to start there. Interest was aroused by the claim put forward by Mr. G. C. Calvert with regard to his process for producing synthetic alcohol from water gas. Full details of the method were not divulged by the inventor; but, briefly, it consists in passing water gas mixed with other gases (according to the product required) through special plant, the alcohol being thrown down in a receiver. In the case of methyl alcohol a yield of 80 per cent. of the theoretical is said to be obtained.

In its second memorandum on motor fuel, published at the end of the year, the Fuel Research Board summarised the results of inquiries made in the Dominions and Colonies as to the possible commercial production of alcohol from materials containing sugar or starch, but held out little hope that such production could be in excess of local needs.

In October the experimental works of Low Temperature Carbonisation, Limited, at Barugh, near Barnsley, were thrown open for inspection of the improvements which have been introduced in connection with the plant for making 'Coalite.' Two main difficulties had attended the operation of the earlier plant, one of which was the inability to discharge rapidly the semi-coke from the retort, while trouble was experienced in making the material of such a character as to preclude disintegration when handled and transported.

A new domestic fuel, known as 'Anthra-coal,' attracted some notice during the year. It consists of a dense coke formed by distilling a mixture

of small anthracite coal and coal-tar pitch. The proportion of pitch used in the mixture is about 16 per cent., and when discharged from the carbonising chamber the fuel remains in large and hard masses without tendency to disintegrate.

Tests carried out during the year would seem to indicate that gas producers are certainly practicable for vehicles of the heavy industrial type. A demonstration was given in April with two 3-ton lorries operated with the Parker plant which entails an additional weight of about 400 lbs., or, say, about 8 lbs. to 10 lbs. per b.h.p. The cost of fitting the plant is about £150. About 15 minutes is required to kindle the fire and get the producer in working order. It was pointed out that a 3-ton lorry can carry a full load at the same speed as with petrol, for 100 miles, on a consumption of 300 lbs. of coke, costing 10*s.* 9*d.*, with coke at £4 per ton, whereas the same vehicle, doing the same work, would consume about 17 gallons of petrol. With several three-ton lorries equipped with the plant, which had been running for some time, the fuel costs were given as 1·32*d.* per mile, or 0·35*d.* per net ton-mile. The producers can also be worked on charcoal, or even vegetable refuse, in tropical countries, where coke and petrol are unobtainable except at very high prices. Converted into ton-mile statistics it was shown that the fuel costs averaged 0·15*d.* per gross ton-mile, and 0·36*d.* per net ton-mile.

GAS ENGINEERING.

Early in the year two separate committees were appointed to investigate the situation as regards inert constituents and carbon monoxide, and their findings occasioned a great deal of relief to gas engineers. The Inerts Committee decided that the restriction of incombustibles was unnecessary, though at some future date it might be advisable to reconsider the matter. It was recommended, in fact, that there should be a further inquiry after the industry had had sufficient time to settle down to the new conditions, and a period of grace of three years was proposed. In connection with the limitation of carbon monoxide it will be recalled that a similar inquiry was held in 1898, when restriction was advocated. Sir William Pearce presided over the committee of last year; and, though considerable evidence was brought forward on behalf of those who supported restriction, it was inferred that interference at that juncture might hamper economic development, and it was decided to recommend no alteration of existing practice.

Instruments designed for the purpose of giving a continuous record of the calorific power of towns' gas have assumed a new and considerable importance under the Gas Regulation Act, for the Act prescribes that the official testing apparatus shall in the case of those undertakings selling more than 100 million cubic feet of gas per annum include a recording calorimeter. During the past year the regulation was not enforced, for the Gas Referees were unable to come to a definite decision as to whether or not the recording instruments available were sufficiently accurate and sensitive to warrant their use for penalty purposes. Trials were made with a number of the better-known instruments, and considerable interest

was displayed in the model upon which Professor C. V. Boys (one of the Referees) has been at work for some time.

In the Metropolitan area the system was adopted of taking spot tests for calorific power at intervals throughout each day (*i.e.* in the case of the South Metropolitan Gas Company it was prescribed that three tests should be taken daily at intervals of not less than three hours between each test), the average of the readings representing the calorific power of the gas as supplied.

An examination of the available carbonisation systems indicates that in the way of producing cheap therms the ' complete gas ' plant is without rival, providing that consistent working results can be obtained which are commensurate with theoretical conceptions. During the past year the improved results obtained with the steamed vertical retort placed this system in the forefront of carbonisation processes. Research was continued by both the Fuel Research Board and the Gas Investigation Committee, and it was a matter of some interest to note that in parallel experiments the results of the two bodies were not altogether in agreement.

A report which must be looked upon as classical as regards its relation to the technical development of carbonisation was that issued during June by the Director of Fuel Research (Sir George Beilby). It had been common knowledge for some years that an enhanced yield of therms was assured with steaming so long as gas having a calorific power of from 400 to 450 B.Th.U. could be established as a saleable commodity. But it was not equally certain what would be the effect of steaming on the other products. It can now be said that there are also gains in the yields of tar and ammonia. Some sacrifice in the quantity and perhaps the quality of the coke must be faced, but is more than compensated for by the gains in the other products. So far as cost of labour is concerned, the greatly increased turnover per retort removes this item from the debit to the credit side of the account, even if more highly skilled workers are employed. Sir George Beilby concluded his report with the confident assertion that by moderate steaming at moderate temperatures the output of therms in the form of gas of good and saleable quality from a unit plant can be greatly increased, while the cost per therm will be correspondingly reduced. Provisionally, he regarded 20 per cent. of steam as representing the upper limit to which steaming could be economically carried, but pointed out that the figure must be definitely determined for different coals.

In practical operation the efficiency of water-gas plants continued to be improved, the most noteworthy features being the increased attention given to ' self-steaming ' processes effected with the aid of a waste heat boiler, and the introduction of a Davison and Partner controller for automatically effecting graduation of steam flow in accordance with the temperature of the fuel bed.

In the final report of the Nitrogen Products Committee, which was issued in August, reference was made to the use of coke for boiler firing. It was stated that boilers fired with broken gas coke and coke breeze were becoming more numerous, and with properly arranged furnaces and forced

draught were giving good results. From data supplied by users and by boilermakers it appears that thermal efficiencies of about 70 per cent. for a boiler alone can be obtained, and the Committee expressed the opinion that with the addition of superheaters and economisers the average working efficiency should rise to about 75 per cent. The results, however, must be largely dependent upon the amount of moisture in the coke and upon the draught available.

The principle of selling gas by 'therms' has definitely removed any incentive to operate the 'stripping' process, for it is apparent that benzene vapour is now a far more valuable product than liquid benzol. The difficulty, therefore, which was experienced in obtaining supplies of this motor fuel is likely to remain.

OIL AND ITS USE.

In the oil industries the past year was one full of remarkable contrasts as compared with its predecessor. During 1920, records of all kinds in the United States petroleum industry were broken, and, according to the U.S. Geological Survey, the domestic production reached the startling total of 443 million barrels, or an increase approaching 20 per cent. over the previous year. This remarkable advance in output was mainly due to the stimulus of high price levels, which resulted in the working of many small wells, the cleaning out of old ones, and intensive drilling in fields where under ordinary conditions the prospective returns would not be deemed commensurate with the risk. During at least a portion of 1921, however, it would seem that the oil industry in the States was in a condition of chaos; not only was the situation affected by a substantial decline in wholesale prices, but it was influenced by the general trade stagnation, tightness of money, and struggle for supremacy which exists between producers and refiners.

In England, so far as the well-known Hardstoft boring was concerned, it was stated in March that 500 tons of crude oil had been produced from this well and had been sold to the Anglo-American Company for £22 10*s.* per ton. It was anticipated that the yield could be increased by pumping, and arrangements were made for carrying out a pumping test as soon as the necessary plant could be obtained. Towards the end of the year it was announced that the several wells in Derbyshire which had failed to yield oil were to be plugged, while the Staffordshire well at Apedale was also abandoned. In fact, only two borings were continued by the Government through its petroleum managers—namely, those at Werrington, in North Staffordshire, and at D'Arcy in Scotland. At the West Calder well in Scotland, boring was suspended some time ago, when the well had reached a depth of some 4,000 ft., but in this case there was some prospect of experiments being resumed.

Considerable interest attached to the huge plant at Skewen, near Swansea, although reticence continued to be observed as to the details of the Anglo-Persian Oil Company's intentions. Operations began in March, and between then and October the importation of crude and other oils exceeded 200,000 tons. Pipe lines were run between the Llandarcy

refineries and Swansea docks, and a new development arising out of the establishment of the works was the bunkering of ships with oil.

In a paper before the Institution of Petroleum Technologists, Mr. A. Beeby Thompson discussed the chief sources of waste in oil-fields, and gave a brief description of the ways and means of reducing losses, improving extraction ratios, and lowering costs.

Renewed attention was given to the problem of converting mineral oils into products bearing the characteristics of vegetable and animal oils, or into the fatty acids required for soap manufacture.

In spite of its many advantages, oil found some difficulty in holding its own in the latter part of the year, when certain grades of coal were obtainable at so low a price as 21*s.* per ton. In these circumstances, in some instances there was a reversion to the use of coal. As regards comparative costs of operation of stationary boilers some interesting figures were given by the engineer of the Hull Corporation Tramways. In this case the oil used had a calorific power of 18,750 B.Th.U. per lb., and its cost was £5 5*s.* per ton. The amount consumed per unit of electricity generated was 2·17 lbs., and the cost per unit was 1·223*d.* In the case of coal the quantity consumed per unit was 3·6 lb., which gave a price per unit of 0·86*d.* For fuel only, therefore, coal proved the cheaper, but if the many subsidiary advantages of oil had been taken into account there would probably have been little difference between the two systems.

In the application of oil fuel to locomotive firing, experience showed that the efficiency of oil compared with coal under service conditions is 1·75 to 1, when all factors are taken into account.

NITROGEN PRODUCTS.

Chief interest attaches to the work conducted by Claude, who has demonstrated the possibility of employing extraordinarily high pressure for the direct synthesis of ammonia. Experimental data have shown that for a given temperature the proportion of nitrogen and hydrogen remaining combined under conditions of equilibrium increases rapidly with the rise of pressure, and the lower the temperature the higher the proportion of combination. Claude finds it most effective to work at about 600° C., and he uses a pressure of nearly 6 tons per sq. in. in contrast with the 1·5 tons per sq. in. employed by Haber. A large-scale Claude plant has been in operation in France for some time, and in this country the Cumberland Coal, Power, and Chemicals Company recently acquired three collieries with coke-oven plant capable of dealing with 1,000 tons of coal per week, the gas from which will be employed in a Claude plant to be erected in Cumberland. In connection with hydrogen production Claude showed that, starting with coke-oven gas, the application of ether as a solvent at pressures of about 1,000 atmospheres and temperatures of about −50° C. very readily yields hydrogen containing less than 0·2 per cent. of carbon monoxide.

The British Cyanides Company continued at Birmingham their large-scale experiments on the fixation of nitrogen by the barium process; but, while these experiments were to an extent successful, no conclusions as to

the commercial applicability of the method were arrived at. The works at Dagenham, erected by the Nitrogen Products Company during the war, for the manufacture of ammonium nitrate from cyanamide by the Ostwald process, were closed down during the year. The Bucher process for the production of cyanides was handicapped by the serious nature of the corrosion which occurs in the plant. Before it can be considered successful, therefore, considerable progress must be made in structural design.

AERONAUTICS.

Among the machines which, although not yet in actual use, were designed during 1921 are the two de Havilland biplanes, D.H.32 and D.H.34. These two types are very similar, except for their engines. The former has a Rolls-Royce Eagle, and carries seven or eight passengers; while the 34 has a Napier Lion, and carries 10 passengers or a cargo of 2,000 lbs. at a cruising speed of about 105 miles an hour. Compared with the majority of machines that have been in use during 1921, this is an excellent performance, especially coupled with the very reasonable power expenditure per passenger carried. As several of these machines have been ordered for use during this year, a much better economy in running is expected on the London-Paris service. Another de Havilland machine which gives promise of great things, although it is at present in the experimental stage, is the D.H.29, a cantilever monoplane with cabin accommodation for 10 passengers; this machine is also fitted with a Napier Lion engine, and its power expenditure is only 45 h.p. per passenger carried, which is very reasonable in view of the high performance of the machine.

Of other purely commercial machines built during 1921 mention may be made of the Bristol 10-seater, also with Napier engine, which has accommodation in its cabin for eight passengers, while if desired an extra passenger can be carried in the pilot's cockpit. Used as a cargo machine the capacity is slightly over 2,000 lbs., and the cruising speed is well above 100 miles an hour, so that the Bristol should also do good work when it is put on the air service in the spring.

It is satisfactory to be able to record that the unit form of construction has gained considerably in favour, owing probably to a closer co-operation between those who build aeroplanes and those who run them. With the engine so mounted that it can be removed as a complete unit, with its cowling, oil tank, &c., by undoing a few bolts and disconnecting the petrol pipes, the task of changing an engine is greatly simplified. Thus an aeroplane need not be kept idle while its engine is being overhauled.

A very exhaustive series of experiments have been carried out on the Handley Page slotted wing, and it has been found that not only the shape of the slot but also its angle and the size of the slot in a wing have a very marked effect on the results. Maximum lift coefficients of 2 (absolute) have been reached, but these occur at very large angles and with a multi-slot arrangement. Even with a single slot, however, and with ailerons so mounted that the slot between them and the main wing is opened or closed as the aileron is pulled down or up, it has been found that an increase in

lift of about 60 per cent. is attainable. This means, according to some calculations made by Mr. Handley Page, that for a machine of the usual dimensions, having a landing speed of 50 miles an hour and a maximum speed of 130 miles, the power required is reduced from 346 h.p. to 208 h.p. The resulting economy in running is very great, and when further experiments have been made on the gear for opening and closing the slots such wings should soon come into general use.

As regards what might be termed normal development, two outstanding events have taken place in the aero engine world. One was the production, by the Napier firm, of a single-power unit developing 1,000 h.p. The Napier Cub marks the high-water mark in single-power units, and its application will follow in the ordinary course of events as soon as certain of its infant ailments have been remedied. The experience of the last year appears to indicate that twin-engined machines are no more reliable than are single-engined ones, and it may therefore be that in the future the twin-engined aeroplane will disappear. Certainly, if sufficient reliability can be provided in one unit, it is more efficient than two placed on the wings. The Napier Cub has not yet had an opportunity of proving itself in practice, but probably more will be heard of it shortly.

The second event was the success of the Bristol Jupiter in passing its Air Ministry's type tests. These are very rigorous, and the Jupiter is the first large air-cooled engine to pass them. This is a splendid testimony to the excellence of the engine, and, given the reliability which the tests appear to indicate it possesses, the air-cooled engine is simpler to run than the water-cooled, there being no radiator, water, or piping to look after. There are rumours of several commercial types of machines being fitted with this engine in the spring.

The world's altitude record was beaten and a new one established, by the American airman, Lieutenant Macready, who reached a corrected altitude of 40,800 ft. He was flying a Lepere biplane (the same as that used by Schroeder in the previous record altitude flight) with a Liberty engine fitted with a supercharger and a variable pitch airscrew.

CEMENT AND CONCRETE INDUSTRY.

The Concrete Utilities Bureau have continued their useful work of making known the many uses of Portland cement concrete. Their exhibit at the Royal Agricultural Show, held at Derby, was a striking illustration of the surprisingly varied purposes to which this material is applicable. A similar demonstration, but of permanent character, was provided by the collection of concrete products at Grosvenor Road, where over 300 exhibits were on view. A recent extension of the activities of the Bureau takes the form of a travelling exhibit which will visit all the more important agricultural shows during the season. The first visit was made to the Altrincham Show, where much interest was aroused by various concrete products and by demonstrations of concrete moulding. The propaganda work of the Bureau also includes the issue of numerous pamphlets, and during last year the first book in Great Britain on the

subject of concrete roads was issued for the Bureau by Concrete Publications, Limited.

Concrete roads continue to make steady progress in different parts of the country. In one London borough, where 25 roads have been remade in concrete, 15 other roads are being similarly treated. The most important example, however, is the new north circular road, starting at Ealing and passing through Willesden and Edmonton to the East End, whence it is proposed to continue the highway to Southend. In its final form this road will include two 24 ft. roadways, a 20 ft. roadway for tramway or high-speed traffic, and two 16 ft. footways. The part now under construction for the Middlesex County Council comprises only one 24 ft. roadway with suitable provision for pedestrians.

The need for improved bridges has been duly recognised by the Ministry of Transport, under whose sanction various reinforced concrete bridges were constructed or begun during last year. One of these is Muskham Bridge, near Newark, carrying the Great North Road over the Trent, and including two 100 ft. span river arches. Another bridge of greater magnitude is that near the mouth of the River Loughor, in South Wales. This structure will be 720 ft. in length, with eighteen 40 ft. girder spans, and it is being built in two parallel halves, so that a roadway may be kept open for traffic continuously.

The British Reinforced Concrete Engineering Company, of Manchester, were engaged in constructing arterial roads in Middlesex and several main roads in provincial towns.

One of the most important works carried out by Messrs. Christiani and Neilsen was a jetty at Purfleet for Messrs. Jurgens. The jetty has an arm extending for a length of 652 ft. at right angles to the shore and measuring 31 ft. in width. At the end of this arm is the jetty proper, 525 ft. long by 40 ft. wide. The structure is founded on 389 reinforced concrete piles, ranging up to 75 ft. long, and is intended for use by ships up to 10,000 deadweight capacity.

In London, the Coignet system was adopted in the interior construction of a large new building for a firm of opticians in Great Portland Street. The walls of this building are also of concrete, faced with stone on the principal façade. No bricks were used, as it was one of the conditions laid down when the plans were sanctioned that brickwork should be eliminated so as to obviate any hindrance to the execution of housing schemes.

The Expanded Metal Company supplied considerable quantities of their material as reinforcement for foundations, floors, roofs, staircases, galleries, and other structural details in buildings, and also for employment in various classes of engineering construction.

Some of the more important works carried out by Johnson's Reinforced Concrete Engineering Company, of Manchester, were a jetty on the Thames for the British Petroleum Company, the Barton Electric Power Station and gasworks extensions for the Manchester Corporation, extensions for the Scunthorpe gasworks, a building at an approximate cost of £100,000 for the Co-operative Wholesale Society at Irlam, and a hydro-electric power station at Linton Falls, including the construction of extensive retaining walls and pile foundations for the turbine house and other buildings.

The London Structural Company were engaged during the early part of 1921 in the construction of concrete houses under the 'Dorlonco' patent, and were responsible for the production of the housing schemes for Chichester, Banbury, and High Wycombe. The company also completed machine shops and warehouses, covering 25,000 sq. ft., in Whitechapel, and specially lined tanks for the storage of wine, beer, and other liquids.

Two very large warehouses, completed by Messrs. L. G. Mouchel and Partners for the tobacco trade, represent 4,600,000 cu. ft. and 2,520,000 cu. ft. capacity respectively. Office buildings of considerable magnitude were constructed in South Wales.

Messrs. J. and W. Stewart erected some concrete dwelling-houses for demonstration purposes at Acton and Belfast, grain silo and flour mill buildings in Dublin, a mill building and various bunkers for cement works in Ireland, a turbine house and refinery for oil works, a pit-head gear frame, and concrete pile foundations in several parts of the country.

The Trussed Concrete Steel Company were responsible for the application of reinforced concrete in the erection of some important buildings, including the Manchester Royal Exchange opened by the King in November, a large shoe factory in course of construction at Kettering, an eight-storey bank building in Waterloo Place for Messrs. Cox and Co., new glass works at Doncaster, and the new grandstand at the All-England Tennis Ground, Wimbledon, this structure having seats for 10,000 spectators, in addition to the usual standing room.

ELECTRICAL ENGINEERING.

In many districts the capital station is already in the making. At Edinburgh, Sheffield, Rotherham, Glasgow, Manchester, Nottingham, and in the London district there are large schemes in progress or in contemplation.

One of the most interesting new types of lamps produced during the past year is the neon-filled lamp, which represents an attempt to provide a lamp of low candle power and small current consumption, which can be used on the ordinary lighting circuit.

With the object of enabling current to be supplied at minimum rates, the whole question of the utilisation of home water resources has been investigated. The final report of the Water Power Resources Committee, issued in December, indicated that some 210,000 kw. of electrical energy could be developed continuously day and night throughout the year at economic costs, from the British water-power schemes which have been investigated. The point of interest is that the commercial output of power of the commercially practicable schemes is equal to about 40 per cent. of the total output in the year 1917–18 of the public electricity supply undertakings operated by steam power, and equivalent to that obtained by the consumption of some 3,000,000 tons of coal. Nothing, even of a preliminary character, was done towards carrying out the Severn barrage hydro-electric scheme.

Work is proceeding on the completion of the London and North Western electrification scheme, and the Brighton Railway is making steady progress with the conversion of an additional mileage of steam routes to electric traction, as a preliminary to the conversion of the main line, for which plans have been prepared. Other companies have had the details of large scale conversions of steam tracks worked out, and the publication of the final report of the Ministry of Transport Electrification Committee in September led to a general renewal of interest in electric railway projects. The Great Eastern, the South Eastern and Chatham, the London and South Western, the Lancashire and Yorkshire, and the North Eastern are all prepared to start work if the necessary capital can be found on reasonable terms. There is a tendency to call a halt until the prices at which the work can be executed fall to a lower level.

The report of the Ministry of Transport Committee makes it clear that the whole of the electrical equipment and rolling stock of home railways will be standardised. This should not only serve to cheapen the cost of the work, but will facilitate the running of through services.

The only railway other than the Brighton which has definitely announced its intention to work main-line services electrically is the North Eastern, and having regard to the likelihood that the work of converting the main York-Newcastle line and other routes may be undertaken in the near future, both freight and passenger electric locomotives have been designed at the Darlington works of that railway. The freight locomotives have been built, and the passenger engine, which is designed for a maximum safe speed of ninety miles an hour, is now under construction. The motor equipment of each of the freight locomotives consists of four totally enclosed motors, each driving an axle through single-reduction twin-gearing. Two motors are fitted in each bogie, and are each wound for 750 volts, the pair in each bogie being connected permanently in series. Each motor is capable of developing 270 b.h.p. at a speed of twenty miles an hour for one hour with forced ventilation, the h.p. for continuous rating being 182. The main traction motors of the passenger engine, which are of the twin armature type, are rigidly fixed to the main frame of the locomotive. The high tension apparatus is arranged in one of the sloping ends, and the other sloping end contains an electric boiler for supplying steam for train heating. The capacity of the locomotive will be 1,800 h.p. one hour rating, or 1,260 h.p. continuous rating. The electrical equipment is being provided by the Metropolitan Vickers Company.

In regard to telephones, perhaps the outstanding achievements of the past year—because financial consideration has had less weight here than elsewhere—are the improvements made or initiated in Post Office telegraph and telephonic equipment. A number of new multiple exchanges operated on the manual system were opened in provincial towns, and seven new exchanges were opened in the London area, while work on many new exchanges and extensions is in progress. New automatic exchanges were completed at Hurley and Ramsay, and have been ordered for Broughty Ferry, Dundee, Southampton, Swansea, and Sketty. Extensions have been ordered for the automatic exchanges at Grimsby, Leeds, Paisley,

and Stockport. The further developments of automatic exchange switching in the Post Office system were the subject of much consideration and study during the year, particularly with reference to the complex conditions applying to London, and, in a less degree, to the principal provincial cities. It is anticipated, as a result, that a considerable advance in the development and extension of automatic systems in Great Britain will be made in the near future. It is claimed that the British Post Office telephone system already serves a larger proportion of its subscribers by means of automatic exchange plant than any other extensive telephone administration in the world.

Considerable progress was also made during the year with the Post Office programme of constructing a complete underground network of main telephone cables. The design of the main cable system has been profoundly modified by the introduction of the thermionic valve and its adaptation as a telephone repeater or relay. Progress in the laying of the new system of main cables is, as the result of this invention, now making rapid progress. About 1,880 miles of ducts and 1,055 miles of main cable, representing a wire mileage of 320,000 miles, had been laid up to the end of 1921.

The use of the Baudot duplex printing telegraph system developed by the Post Office Engineering Department has been considerably extended during the last twelve months, both on the inland telegraph service and on telegraph lines to the Continent. Chief among the latter are the two London-Amsterdam circuits, which for many years were worked with Baudot quadruple simplex sets giving four hand-speed channels per circuit. They are now each equipped with Baudot triple duplex sets giving six hand-speed channels per circuit, an increase in carrying capacity of 50 per cent.

Another important step is the use of Baudot duplex working to serve more than two stations per circuit.

An extensive system of underground cables for the improvement of the telegraph service between important towns is also in course of provision. The lines to France, Belgium, Denmark, Sweden, Norway, America, and other countries are already carried on underground cables in England. Underground cables are now being laid to the coast for the circuits to Holland and Germany.

The cable services to the Continent are supplemented by means of the Post Office wireless stations at Stonehaven and Caister, both of which are now equipped for high-speed transmission at 100 words per minute. Stonehaven communicates with Berlin, Posen, and Budapest; Caister is used for a service to Amsterdam. The Stonehaven-Berlin and Caister-Amsterdam channels are both controlled by land line from the Central Telegraph Office in London, and the former works as a high-speed duplex service. The Aldershot-Cologne wireless service, installed by the Army for the use of the Army of Occupation, is also being used by the Post Office for the same purpose. With distant control from the Central Telegraph Office in London and from the German Post Office to the Cologne station, a high-speed through commercial service is maintained.

The valve in its 'triode' form has become commonplace in reception, various modifications have been introduced, and a 'tetrode' valve, replacing three triodes, has been put into commercial service in the mercantile marine. In transmission the field of the valve has been extended to considerably higher powers, and it is evident that the limit has not yet been reached. There are in use at the present time valve transmitters producing aerial currents of between 300 and 400 amperes, and it is claimed that currents of 1,000 amperes are practicable.

The 1920 recommendation of the Imperial Wireless Telegraphy Committee, in favour of the valve transmitter, has been endorsed by the subsequently appointed committee of experts known as the Wireless Telegraphy Commission, and although the first two of the Imperial stations are equipped with arc transmitters there is little doubt that the valve will be installed in the others. The two stations in question, Leafield, near Oxford, which was opened in August last, and Abu Zabal, near Cairo, which is to be opened shortly, were under construction at the time of the presentation of the Committee's report, and, in view of the probability of international agreement regarding the prohibition of the use of transmitters emitting harmonic waves, it does not seem unlikely that the valve transmitter will be installed eventually at both these stations.

In the United States the multiple-tuned antenna has been introduced, and is installed at the new Long Island station of the Radio Corporation of America. The British Marconi Company has developed a screening system which greatly reduces transmission losses, and is in use at the transatlantic stations at Clifden and Carnarvon.

The past year saw the production of a general purpose commercial type of directional receiver. With this instrument a zero or blind point can be put on a jamming station, and interference, even on the working wavelength, can be cut out by this means in all cases where the direction of the jamming station differs sufficiently from that of the station to be received. Recent experience has shown also that directional reception is of considerable advantage during periods of atmospheric disturbance. The Franklin directional receiving system, which provides three independent zero points, has now been in use at the British transatlantic receiving stations for upwards of a year, and the results obtained with this system, under commercial conditions, leave no doubt that directional reception is to be an important factor in future developments.

The research on which Senator Marconi was engaged during the latter part of 1920 and the beginning of 1921 has resulted in the production of a new receiver designed for auto working. It is understood that this receiver has been in commercial service during the last few months, and that at speeds over forty words per minute the results show a marked improvement over those obtainable with the best apparatus previously available.

METAL INDUSTRIES.

The main subject which received attention on the technical side is the cleaning of blast-furnace gases. Some useful experimental work has been done at Skinningrove, and good results have been obtained from the

plant put up at Jarrow, some statistics concerning which were made public at the meeting of the Iron and Steel Institute. What it has meant in this case is that the power supply for the whole of the works, which formerly had to be bought, is now being obtained from the cleaned waste gases. It is estimated that if the process were generally adopted, from three to four million horse-power could be produced from waste blast-furnace gases, and the electrical equipment of works could be developed at much lower costs than by any other means.

With regard to raw materials, important results have followed the opening up of new British deposits of iron ore in Lincolnshire, Northamptonshire, and elsewhere, while the acquisition by France of areas which have made her the possessor of the largest iron ore resources in Europe has offered new sources to British ironmasters.

An interesting feature of the year was the development of a stainless iron similar to the stainless steel with which engineers are now familiar. The composition of rustless iron (carbon, 0·7; silicon, 0·8; manganese, 0·12; chrome, 11·7; and nickel, 0·57) is, except for a variation in the carbon content, the same as that of the steel possessing similar qualities, and it has properties which should ensure for it a wide range of use.

The greater use which is being made of the electric furnace is an outstanding feature. Among the new installations are the large mixers of 400 and 500 tons capacity acquired by the United Steel Companies and the Parkgate Iron and Steel Company, the new section mill at the works of the last-named company, the new tilting furnace for Frodingham, the Koppers coke oven plant at the United Steel Company's works at Rotherham, and the modern tire plant laid down at Messrs. Cammell, Laird's Penistone works.

An interesting contribution on defects in steel was that made to the Iron and Steel Institute by Mr. H. Brearley, on the welding of steel in relation to the occurrence of pipe blowholes and segregates in ingots.

As in the case of the iron and steel branch, non-ferrous metal manufacturers have devoted a good deal of attention to the investigation of the causes of failure of metals in service. A noteworthy example of work in this field is the research work into the cause of season cracking in brass. The conclusion has been reached that this phenomenon occurs only in material which is maintained in a state of stress either by external constraint or more frequently by internal stress, though it seems probable that some additional agency is required to cause failure. With regard to methods of prevention, the research carried out at Woolwich Arsenal suggests that a suitably controlled low temperature annealing which would not affect the hardness of the material may be the best safeguard. The whole subject of failure in metals under internal stress was brought up at a joint gathering of many interests under the auspices of the Faraday Society. In the case of lead it would appear that where this metal is employed as sheathing for telegraph cables the cause of failure is excessive external strain, and that in season cracking it is impossible to disregard the influence of corrosion as at least a secondary cause. Failures in brass ingots due to casting have also been the subject of experiment, and a

method appears to have been evolved which reduces large percentages of waste to negligible proportions.

Other investigations, the results of which have been made public through the Institute of Metals or elsewhere, include those on the nickel-aluminium-copper alloys with high percentages of copper and on the influence of the addition of lead to gunmetal. The latter research, which was carried out at Messrs. W. H. Allen and Sons, showed that up to about 1·5 per cent. of lead the strength and ductility of sand-cast Admiralty gunmetal is increased, but the hardness diminished. A larger addition of lead brings an increase in hardness and a falling off in the other qualities.

MOTOR CARS.

Manufacturers have concentrated upon economical two- and four-seater cars rated at from 8 to 15 h.p., capable of carrying their loads over any main roads at good average speeds, and yet showing petrol consumptions of from 30 to 40 miles per gallon. Several of the leading large-car makers have entered the field of the smaller or economy car, and are supplementing their larger 20 to 30 h.p. models with others of 10 to 15 h.p. There is also a tendency to extend the light car in each direction ; smaller cars of from 5 to 8 h.p., fitted with two- or four-cylinder engines, are appearing, while at the other end of the scale the 1,500 c.c. class has extended to the 2,000 c.c., or new two-litre class. In France, considerable attention has recently been given to the ultra-light car.

In the 10 to 20 h.p., or average car class, about 90 per cent. of the engines are of the four-cylinder type ; there was no encroachment of the six-cylinder model on this class of car during the past year. The six, straight-eight, **V**-eight, and 12-cylinder engines are characteristic of the higher powered and more expensive cars ; the second of these types has made a noticeable advance in popularity, as a result of its racing successes.

In the two-cylinder type, the horizontal opposed arrangement has proved very satisfactory upon certain light cars produced by well-known large-car manufacturers ; about 25 per cent. of the smallest light cars are now fitted with air- or water-cooled two-cylinder opposed engines.

Sleeve-valve engines appear to be on the increase ; about 20 per cent. of the more expensive types of car are fitted with them, and one or two new patterns show great promise. The rotary valve was represented by one example at last year's motor show.

The side-by-side valve system is still the most popular in the lower and medium sizes of engine ; about 70 per cent. of last year's engines were fitted with such valves. In many cases, however, it has been superseded by the overhead valve, which has gained many fresh adherents in the case of higher powered engines.

The use of detachable cylinder heads is still slowly increasing, and about 50 per cent. of the engines are now thus fitted.

A novelty in engine cooling exists in one successful two-cylinder **V**-type engine, in which the cylinder barrels are made to project into the crank-case, and together with the inner side of the piston are cooled by the oil-spray

in the crank-case, an additional quantity of lubricant being carried for the purpose.

About 50 per cent. of last year's cars were fitted with four speeds, as against about 45 per cent. with three speeds and about 5 per cent. with two speeds or variable gear. An innovation in the disposition of the gear box has been made in the case of one or two well-known light cars, by combining the gear box with the forward end of the torque tube ; this arrangement diminishes the number of universal joints, renders the clutch more accessible, and lessens the engine unit weight.

The straight-bevel drive, which hitherto had practically monopolised the final drive, has been very definitely supplanted by the spiral bevel ; about 70 per cent. of modern cars are now fitted with the latter, as against about 20 per cent. with the straight bevel and 10 per cent. with worm drive.

In clutches the chief change was in the direction of the dry single-plate type. The decline of the leather-cone type was most marked. The multi-plate clutch is retained in Continental and in the larger British cars. About 35 per cent. of last year's cars had the single-plate clutch, about 25 per cent. the fabric-covered cone clutch, about 25 per cent. the multi-plate type, and about 15 per cent. the leather cone type.

As regards the steering, the sector-shaped worm-wheel is being replaced by the complete wheel, so that increased life may be attained by turning the wheel around to an unworn portion when it is worn in one place. An improved design of the Marle's steering system is also finding favour.

LOCOMOTIVES.

One of the most interesting engines of the year is the 4–6–0 four-cylinder type, of which a number has been built for fast goods traffic by the Great Central Railway in its Gorton shops or have been obtained from private builders. These locomotives are similar to the older Valour class of four-cylinder express passenger engines, except as regards the size of the coupled wheels, which are 5 ft. 8 ins. instead of 6 ft. 9 ins. in diameter. The cylinders are each 16 ins. by 26 ins., the boiler pressure is 200 lbs., the evaporative surface 2,044 ft., and the grate area 26 sq. ft. A Robinson superheater is fitted. The engine weighs 81½ tons, and the engine and tender combined 130 tons. Other engines of this class are under construction at Gorton and by outside firms for delivery during the present year, but no more will be ordered from outside firms at present. There are now in hand at Gorton Works 4–6–2 passenger tank engines, with cylinders 20 ins. in diameter by 26 ins. stroke, with 5 ft. 7 ins. coupled wheels ; and 4–4–0 express passenger engines of the 'Modified Director' class, with cylinders 20 ins. in diameter by 26 ins. stroke, and coupled wheels 6 ft. 9 ins. diameter. A Great Central engine of the standard 2–8–0 type during the past year was fitted with a new boiler of special design, giving a firebox of very large capacity. This boiler is intended to be heated by liquid, colloidal or pulverised fuel or bituminous coal. The engine has recently been put into regular service, and is now under observation with oil fuel,

after which trials with colloidal fuels and pulverised and bituminous coal will be made.

A new design of three-cylinder express passenger locomotive was introduced by the Caledonian Railway. The cylinders are all of 18½ ins. diameter by 26 ins. stroke, and piston valves are fitted in conjunction with Walschaert valve gear. One pair of cylinders is placed outside the frame and the other cylinder inside, the outside pair being connected to the middle pair of coupled wheels, and the inside cylinder driving the leading pair. The coupled wheels are 6 ft. 1 in. in diameter, and the wheel base is 15 ft. The tractive effort is large for Caledonian practice, being 28,000 lbs. The tender is of the six-wheeled type, having a water capacity of 4,500 gallons. A number of 4–6–0 two-cylinder express passenger locomotives were also constructed. The weight of the engine and tender of the three-cylinder type in working order is 129 tons, and of the two-cylinder 121½ tons.

The North British Company either at Cowlairs or at contractors' works, including the North British Locomotive Company, have had built nineteen superheater goods engines with cylinders 19½ ins. by 26 ins., two Atlantics, and six 4–4–2 passenger tank engines with coupled wheels 5 ft. 9 ins. in diameter.

The feature of the work done in the Midland locomotive shops is the 0–10–0 engine designed for work on the famous Lickey incline, one of the steepest gradients on any English main line. There are four cylinders cast in pairs all 16¾ ins. in diameter and 28 ins. in stroke. The cross port system is adopted. The piston valves, which by reason of this arrangement can supply both cylinders on one side, are of 10 ins. diameter and are driven by Walschaert gearing. The coupled wheels are of the comparatively small diameter of 4 ft. 7½ ins., but the wheel base is large, being 20 ft. 11 ins. The engine has a tractive effort of no less than 43,212 lbs.

On the Great Western Railway the chief interest in the work at Swindon was the bringing up to date of a mixed traffic engine of the 2–8–0 type. A new boiler was fitted, and the steam admission pipes are now taken through the smoke-box and coupled externally to the cylinders. Ten of these were completed last year, and a number of the same type are now going through the shops. The stock of the 2–6–0 class was considerably augmented, no fewer than seventy-two having been turned out during the twelve months.

At Eastleigh the London and South Western Railway have built a few tank engines which embody new features. Some of these are of the six-wheels and others of the eight-wheels coupled type, the latter being intended for the working of heavy goods trains. The total evaporative surface is 1,406 sq. ft., and a superheater of the Eastleigh pattern is fitted.

ALGEBRA.

Ratio.

Ratio is the relation of one quantity to another in respect of magnitude.

The magnitudes of two quantities of the *same kind* may be compared in two ways :—

(1.) By finding their difference, or how much one is greater than the other. This gives the *Arithmetical Ratio* of the quantities.

(2.) By finding how many times the one contains the other. This determines their *Geometrical Ratio*, or, simply, their *Ratio*.

For example, if a and b be the measures of two quantities, their *Arithmetical Ratio* is $a-b$, and their (*Geometrical*) *Ratio* is $a : b$ or $\frac{a}{b}$; a and b are called the *Terms* of the ratio ; a is called the *Antecedent*, and b the *Consequent*. The ratios $a^2 : b^2$, $a^3 : b^3$, $\sqrt{a} : \sqrt{b}$, and $\sqrt[3]{a} : \sqrt[3]{b}$ are called respectively the *duplicate*, the *triplicate*, the *subduplicate*, and the *subtriplicate* ratio of $a : b$.

If $\frac{a}{b} = \frac{c}{d} = \frac{e}{f} = \cdots$ each of these ratios is equal to $\frac{a+c+e+\cdots}{b+d+f+\cdots}$. The application of this principle greatly simplifies many problems.

Proportion.

Proportion is the equality of two ratios. The ratio of $a : b$ will be equal to $c : d$ if $\frac{a}{b} = \frac{c}{d}$, and the four numbers represented by a, b, c, d are then said to be *proportionals*.

The proportion is usually stated thus :—$a : b = c : d$, or $a : b :: c : d$ (read a is to b as c is to d). The two terms a and d are called the *extremes*, and b and c the *means*.

If a, b, c, d be proportionals, the product of the *extremes* is equal to the product of the *means*. or,

$$ad = bc.$$

Conversely, if $ad = bc$,

$a : b = c : d.$ $\quad a : c = b : d.$ $\quad d : b = c : a.$ $\quad d : c = b : a.$

Also, if $a : b :: c : d$,

$a+b : b = c+d : d.$ $\quad a-b : b = c-d : d.$ $\quad a+b : a-b = c+d : c-d.$

Arithmetical Progression.

An *Arithmetical Progression* is a series of numbers which increase or decrease by a *constant difference*. Thus 1, 3, 5, 7, 9 ; 10, 8, 6, 4, 2 are *arithmetical progressions*, the constant difference being 2 in the first series and -2 in the second.

Let a = the first term of the series. z = the last term. n = the number of terms.
d = the constant difference. S = the sum of all the terms.

$$a = z - d(n-1). \qquad a = \frac{2S}{n} - z. \qquad a = \frac{S}{n} - \frac{d}{2}(n-1). \qquad z = a + d(n-1).$$

$$z = \frac{2S}{n} - a. \qquad z = \frac{S}{n} + \frac{d}{2}(n-1). \qquad n = \frac{z-a}{d} + 1. \qquad n = \frac{2S}{a+z}.$$

$$d = \frac{z-a}{n-1}. \qquad d = \frac{(z+a)(z-a)}{2S-a-z}. \qquad d = \frac{2(S-an)}{n(n-1)}. \qquad d = \frac{2(zn-S)}{n(n-1)}.$$

$$S = \frac{n(a+z)}{2}. \qquad S = \frac{(a+z)(z+d-a)}{2d}. \qquad S = n\left[a + \frac{d}{2}(n-1)\right].$$

$$S = n\left[z - \frac{d}{2}(n-1)\right]. \qquad a = \frac{d}{2} \pm \sqrt{\left(z + \frac{d}{2}\right)^2 - 2dS}.$$

$$z = \frac{d}{2} \pm \sqrt{\left(a - \frac{d}{2}\right)^2 + 2dS}. \qquad n = \frac{1}{2} - \frac{a}{d} \pm \sqrt{\left(\frac{1}{2} - \frac{a}{d}\right)^2 + \frac{2S}{d}}.$$

$$n = \frac{1}{2} + \frac{z}{d} \pm \sqrt{\left(\frac{1}{2} + \frac{z}{d}\right)^2 - \frac{2S}{d}}.$$

When the series is a decreasing one make the first term $= z$, and the last term $= a$.

The *Arithmetical Mean* of two quantities, A and B, $= \frac{A+B}{2}$.

Geometrical Progression.

A *Geometrical Progression* is a series of numbers which increase or decrease by a *constant factor*, or *common ratio*. For example, 2, 4, 8, 16, 32 ; 4, $-\frac{1}{2}$, $\frac{1}{16}$, $-\frac{1}{128}$, $\frac{1}{1024}$, are Geometrical Progressions, the constant factor being 2 in the first series and $-\frac{1}{8}$ in the second.

Let a = the first term. z = the last term. n = the number of terms.
r = the constant factor. S = the sum of the terms.

$$a = \frac{z}{r^{n-1}}. \qquad a = S - r(S-z). \qquad a = S\frac{r-1}{r^n-1}. \qquad z = ar^{n-1}.$$

$$z = S - \frac{S-a}{r}. \qquad z = S\left(\frac{r-1}{r^n-1}\right)r^{n-1}. \qquad r = \sqrt[n-1]{\frac{z}{a}}. \qquad r = \frac{S-a}{S-z}.$$

$$ar^n + S - rS - a = 0. \qquad S = \frac{a(r^n-1)}{r-1}. \qquad S = \frac{a(1-r^n)}{1-r}. \qquad S = \frac{rz-a}{r-1}.$$

$$S = \frac{z(r^n-1)}{(r-1)r^{n-1}}. \qquad n = 1 + \frac{\log z - \log a}{\log r}. \qquad n = 1 + \frac{\log z - \log a}{\log (S+a) - \log (S-z)}.$$

$$n = \frac{\log [a + S(r-1)] - \log a}{\log r}. \qquad n = 1 + \frac{\log z - \log [zr - S(r-1)]}{\log r}. \qquad S = \frac{z\sqrt[n-1]{z} - a\sqrt[n-1]{a}}{\sqrt[n-1]{z} - \sqrt[n-1]{a}}.$$

The *Geometric Mean* of two quantities, A and B, $= \sqrt{AB}$.

Harmonical Progression.

Quantities are said to be in *Harmonical Progression* when any three consecutive terms being taken, the first is to the third as the difference between the first and second is to the difference between the second and third. Thus, if a, b, c be the consecutive terms in a series, then, if $a : c :: a - b : b - c$, a, b, c are in harmonical progression. If quantities are in harmonical progression, their reciprocals are in arithmetical progression.

There is no method by which the sum of an harmonic series can be found.

The *Harmonic Mean* of two quantities, A and B, $= \frac{2AB}{A+B}$.

Simple Interest.

Interest is money paid for the use of other money lent for a certain time at a fixed rate per cent.

Let P = the *Principal*, or money lent, in pounds. R = the *Rate per Cent.*, or interest of £100 for one year. I = the *Interest*. A = the *Amount*, or principal + interest. T = the *Time* in years.

Then

$$I = \frac{P \times T \times R}{100}. \qquad R = \frac{100 \times I}{PT}. \qquad P = \frac{100 \times I}{RT}. \qquad T = \frac{100 \times I}{PR}.$$

$$A = P + I = \frac{P(100 + RT)}{100}. \qquad P = \frac{100 \times A}{100 + RT}.$$

If the *Time* (T) be given in *months*, *weeks*, or *days*, multiply the 100 in the above equations by 12, 52, or 365 as the case requires.

Compound Interest.

In *Compound Interest*, the interest due at the end of the first period is added to the principal, and the *amount* thus obtained is taken as the principal in calculating the interest for the next period, and so on.

Let P = Principal. A = Amount. r = Interest on £1 for a year or given period. n = Number of years, or periods.

Then

$$A = P(1+r)^n. \qquad P = \frac{A}{(1+r)^n}. \qquad r = \sqrt[n]{\frac{A}{P}} - 1. \qquad n = \frac{\log A - \log P}{\log (1+r)}.$$

Compound Interest Table.

Showing the sum to which £1 will increase at *Compound Interest* during any number o years not exceeding 50; interest being calculated to and added on at the end of every year.

50	3·43711	4·383906	7·106683	11·467400	18·420154

Present Value and Discount.

The *present value* or *present worth* of an amount due at some future time is the sum which, together with its interest from the present time to the time when payment is due, will be equal to the given amount. For example, the present value of £412 due 9 months hence at 4 per cent. simple interest is £400, since £400 + its interest for 9 months = £412. *True discount* is the difference between the amount and its present value; or, in other words, it is the *interest* on the *present value* for the given period. Ordinary commercial, or *banker's discount*, is *interest* on the *amount* of the debt, and is therefore always greater than the true discount. In the above example the true discount of £412 = £12; the banker's discount = £12 7*s.* $2\frac{2}{5}$*d.*

Let A = amount of debt. P = present value. D = true discount. D_b = banker's discount.
r = interest of £1 for one year. n = number of years.

Then

$$A = P(1 + nr). \qquad A = \frac{D(1 + nr)}{nr}. \qquad P = \frac{A}{1 + nr}.$$

$$D = A - P = A - \frac{A}{1 + nr} = \frac{Anr}{1 + nr}.$$

$$D_b = Anr. \qquad r = \frac{A - P}{Pn}. \qquad n = \frac{A - P}{Pr}.$$

Annuities.

An *annuity* is a fixed sum of money paid periodically. An annuity, N, is left unpaid for n years; to find the whole amount, A, allowing simple interest (interest on £1 for one year = r) :—

$$A = nN + \frac{n(n-1)}{2} rN.$$

If compound interest allowed :—

$$A = \frac{(1 + r)^n - 1}{r} N.$$

To find the present value, P, of an annuity, N, to continue for n years, allowing compound interest :—

$$P = \frac{1 - (1 + r)^{-n}}{r} N.*$$

[If simple interest be reckoned in calculating the present value of an annuity, the results obtained will be untrustworthy.]

The present value of a perpetual annuity is obtained by making n infinite in formula (*), which then becomes

$$P = \frac{N}{r}.$$

If mN is the present value of an annuity, N, the annuity is said to be worth *m years' purchase.* The number of years' purchase, m, of a perpetual annuity is :—

$$m = \frac{1}{r} = \frac{100}{\text{rate per cent.}}.$$

A debt, D, bearing compound interest is diminished by an annual payment, N; to find the debt, d, after n years, and the time, m, when it will be fully paid :—

$$d = \frac{(Dr - N)(1 + r)^n + N}{r}.$$

$$m = \frac{\log N - \log (N - Dr)}{\log (1 + r)}.$$

If $N = Dr$, then $m = \infty$, or the debt D will never be paid. If $N < Dr$ the debt will be increased. To find the yearly payment, N, which will pay a debt, D, in n years at r per cent. compound interest :—

$$N = \frac{Dr(1 + r)^n}{(1 + r)^n - 1}.$$

ANNUITY TABLE.

Showing the Amount of an Annuity of £1 for any number of Years not exceeding 50, and for various rates of Interest.

100	·116	·081	·056	·038	·026	·018	100

Example :—

Required the amount which should be set aside at the end of each year to form a Fund, at 4 per cent. interest, to replace, in 20 years, 5,000*l.* expended in the installation of electric light plant.

$$\text{Annual amount} = \frac{5{,}000l.}{100} \times 3{\cdot}358 = 167{\cdot}9l. = 167l.\ 18s.$$

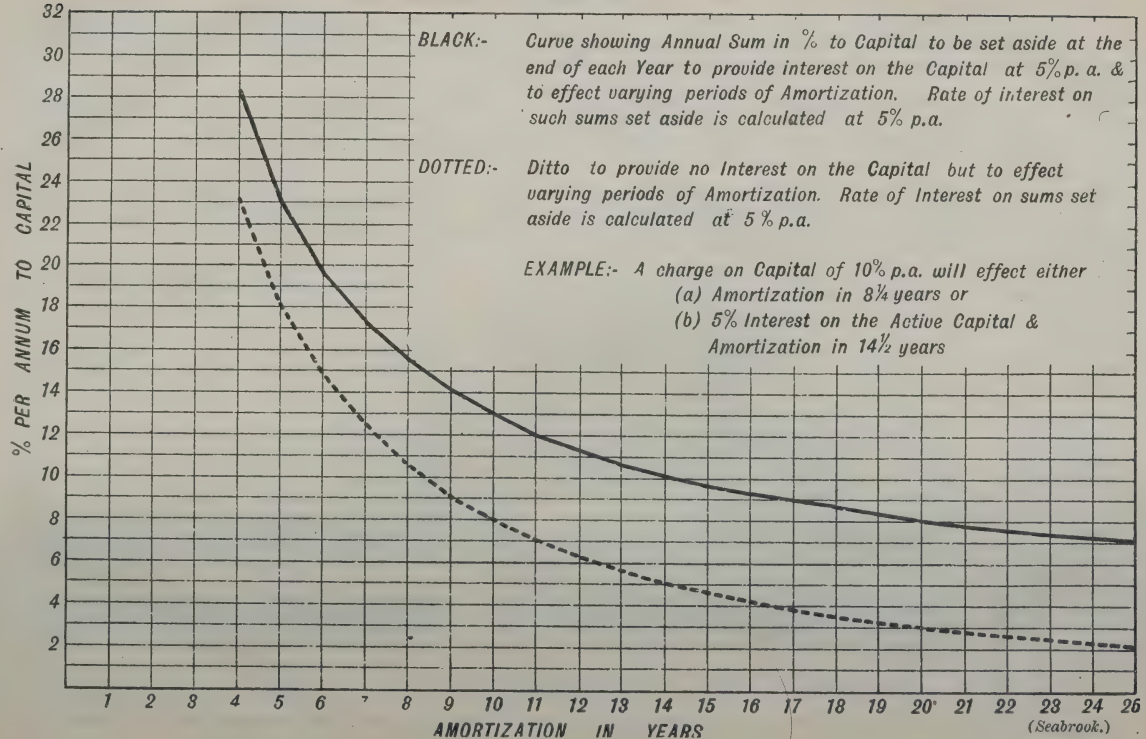
Formula :—

$$A = \frac{R}{\left(1 + \frac{R}{100}\right)^{n} - 1},$$

where,

A = amount; R = rate per cent. per annum; n = number of years.

If the annual amount to be set aside at the *beginning* of each year is required, then the formula is :—



$$A = \frac{R}{\left(1 + \frac{R}{100}\right)^{n} - 1} \times \frac{100}{100 + R} = \frac{R}{\left(1 + \frac{R}{100}\right)^{n+1} - \left(1 + \frac{R}{100}\right)}$$

Present Value Table.

Present value of £1 due at the end of any one of a given number of years at various rates of interest per cent.

No. of Years.	1½ per cent.	1¾ per cent.	2 per cent.	2½ per cent.	3 per cent.	3½ per cent.	4 per cent.	4½ per cent.

BLACK:- Curve showing Annual Sum in % to Capital to be set aside at the end of each Year to provide interest on the Capital at 5% p. a. & to effect varying periods of Amortization. Rate of interest on such sums set aside is calculated at 5% p.a.
DOTTED:- Ditto to provide no Interest on the Capital but to effect varying periods of Amortization. Rate of Interest on sums set aside is calculated at 5 % p.a.
EXAMPLE:- A charge on Capital of 10% p.a. will effect either
(a) Amortization in 8¼ years or
(b) 5% Interest on the Active Capital & Amortization in 14½ years

AMORTIZATION IN YEARS
(Seabrook.)

Binomial Theorem and Series.

This theorem is exceedingly useful in many algebraical operations, particularly in finding the terms of an infinite quotient; it enables the mechanical labour of multiplication in working out the expansion of an expression of the form $(a+b)^n$ to be greatly abridged.

$$(a+b)^n = a^n + na^{n-1}b + \frac{n(n-1)}{1.2}a^{n-2}b^2 + \frac{n(n-1)(n-2)}{1.2.3}a^{n-3}b^3 + \&c.$$

$$(1+x)^n = 1 + nx + \frac{n(n-1)}{1.2}x^2 + \frac{n(n-1)(n-2)}{1.2.3}x^3 + \&c.$$

$$\left(1+\frac{1}{n}\right)^n = e, \text{ if } n \text{ is very large.} \qquad e = 2{\cdot}71828.$$

$$\frac{1}{1+x} = 1 - x + x^2 - x^3 + x^4 - x^5 + \&c.$$

$$\log_e x = x - 1 - \tfrac{1}{2}(x-1)^2 + \tfrac{1}{3}(x-1)^3 - \tfrac{1}{4}(x-1)^4 + \&c.$$

$$\log(1+x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \&c.$$

$$a^x = 1 + Ax + \frac{A^2x^2}{1.2} + \frac{A^3x^3}{1.2.3} + \frac{A^4x^4}{1.2.3.4} + \&c.,$$

where $A = \log_e a$.

Also,

$$a^x = 1 + x\left\{a - 1 - \tfrac{1}{2}(a-1)^2 + \tfrac{1}{3}(a-1)^3 - \tfrac{1}{4}(a-1)^4 + \&c.\right\}.$$

$$e^x = 1 + x + \frac{x^2}{1.2} + \frac{x^3}{1.2.3} + \frac{x^4}{1.2.3.4} + \&c.$$

$$\sin h = h - \frac{h^3}{1.2.3} + \frac{h^5}{1.2.3.4.5} - \frac{h^7}{1.2.3.4.5.6.7} + \&c.$$

$$\cos h = 1 - \frac{h^2}{1.2} + \frac{h^4}{1.2.3.4} - \frac{h^6}{1.2.3.4.5.6} + \&c.$$

Square Root.

To find $\sqrt{N}$ when N is very nearly a square :—

$$\text{If } N = a^2 + x, \ \sqrt{N} = a + \frac{x}{2a}, \text{ if } x \text{ is small and } a \text{ great.}$$

From which we obtain this practical rule :—'Having found the square root of the integer part of a number, consisting partly of integers and partly of decimals, the remainder of the root may be found by dividing $N - a^2$, *i.e.* x, by $2a$.'

EXAMPLE.—Find the square root of 124·25.

$$\text{Here } N = 121 + 3{\cdot}25 = a^2 + 3{\cdot}25 \ ; \ \therefore a = 11.$$

$$\frac{x}{2a} = \frac{3{\cdot}25}{22} = {\cdot}14. \quad \therefore \ \sqrt{N} = 11{\cdot}14.$$

Again, if $N = a^n + b$, and $\sqrt[n]{N}$ be required, then

$$\sqrt[n]{N} = a\left\{1 + \frac{b}{na^n} - \frac{n-1}{2n^2}\cdot\frac{b^2}{a^{2n}} + \frac{(n-1)(2n-1)}{1.2.3n^3}\cdot\frac{b^3}{a^{3n}} + \&c.\right\}.$$

EXAMPLE.—Find the 5th root of 35.

$$\text{Here } N = 35 = 32 + 3 = 2^5\left(1 + \frac{3}{2^5}\right);$$

$$\therefore \ a = 2, \ b = 3, \ n = 5.$$

$$\therefore \ \sqrt[5]{35} = 2\left\{1 + \frac{3}{5 \times 32} - \frac{4 \cdot 3^2}{2 \times 5^2 \times (32)^2} + \frac{4 \cdot 3 \cdot 3^3}{2 \times 3 \times 5^3 \times (32)^3} - \&c.\right\}.$$

Permutations.

The different arrangements that can be made of any number of quantities are called *Permutations.*

If ${}^nV_r$ represent the variations of n things taken r together,

$${}^nV_r = n(n-1)(n-2)(n-3) \ \ldots \ (n-r+1).$$

The number of *permutations* of n things (all different), *i.e.*, of n things taken *all* together, is equal to the product of the first n digits.

Combinations.

The different collections that can be made of any number of things, without regard to their order, are called *combinations*.

If ${}^nC_r$ be the number of combinations of n things taken r together, then

$$ {}^nC_r = \frac{n(n-1)(n-2)\ \ldots\ \{n-(r-1)\}}{1.2.3\qquad\qquad r}. $$

The number of combinations of n things taken r together equals the number of combinations of n things taken $(n-r)$ together.

Miscellaneous.

$a^0 = 1.$ $\quad \frac{a}{0} = \infty.$ $\quad \log_a a = 1.$ $\quad$ If $a^x = b$, $x = \frac{\log b}{\log a}.$ $\quad$ If $e^x = b$, $x = \log_e b.$

DIFFERENTIAL AND INTEGRAL CALCULUS.

DIFFERENTIAL CALCULUS.

General Formulæ.

Differential Coefficient of a Simple Function :— $\quad u = x^n + c \qquad \frac{du}{dx} = nx^{n-1}.$

If $u = az$, where z is a function of x, and a is a constant,

$$ \frac{du}{dx} = a\frac{dz}{dx}. $$

Differential Coefficient of a Product :—The differential coefficient of the product of the functions equals the sum of the products of each function into the differential coefficient of the other.

$$ u = zv \qquad \frac{du}{dx} = z\frac{dv}{dx} + v\frac{dz}{dx}. $$

Differential Coefficient of a Quotient :— $\quad u = \frac{z}{v} \qquad \frac{du}{dx} = \frac{1}{v^2}\left\{ v\frac{dz}{dx} - z\frac{dv}{dx} \right\}.$

$u = z^n \qquad \frac{du}{dx} = nz^{n-1}\frac{dz}{dx}.$ $\qquad u = (a^2 + x^2)^n \qquad \frac{du}{dx} = n(a^2 + x^2)^{n-1}2x.$

Differential Coefficient of a Square Root.—The differential coefficient of the square root of any quantity is equal to the differential of the quantity under the square root divided by twice the square root of the quantity itself.

$$ u = \sqrt{a + bx + cx^2} \qquad \frac{du}{dx} = \frac{b + 2cx}{2\sqrt{a + bx + cx^2}}. $$

$u = x(a - x) \qquad \frac{du}{dx} = a - 2x.$ $\qquad u = \frac{x}{\sqrt{1 + x^2}} \qquad \frac{du}{dx} = \frac{1}{(1 + x^2)^{\frac{3}{2}}}.$

$u = \sqrt{\frac{1 - \sqrt{x}}{1 + \sqrt{x}}} \qquad \frac{du}{dx} = -\frac{1}{2(1 + \sqrt{x})\sqrt{x - x^2}}.$ $\qquad u = (1 + x)\sqrt{1 - x^2} \qquad \frac{du}{dx} = \frac{1 - x - 2x^2}{\sqrt{1 - x^2}}.$

Angular Functions.

$u = \sin x \qquad \frac{du}{dx} = \cos x.$ $\qquad u = \cos x \qquad \frac{du}{dx} = -\sin x.$

$u = \tan x \qquad \frac{du}{dx} = 1 + \tan^2 x = \sec^2 x = \frac{1}{\cos^2 x}.$

$u = \sec x \qquad \frac{du}{dx} = \tan x \sec x.$ $\qquad u = \text{versin } x \qquad \frac{du}{dx} = \sin x.$

$u = \cot x \qquad \frac{du}{dx} = -(1 + \cot^2 x) = \frac{1}{\sin^2 x} = -\text{cosec}^2 x$

$u = \text{cosec } x \qquad \frac{du}{dx} = -\cot x \text{ cosec } x.$

$u = \sin z \qquad \frac{du}{dx} = \cos z\frac{dz}{dx}$ $\qquad u = \cos z \qquad \frac{du}{dx} = -\sin z\frac{dz}{dx}$; and so on.

EXAMPLE.—Find that angle (x) which increases twice as fast as its sine.

Let $u = \sin x$; $du = \cos x \,.\, dx$.

But $du = \frac{1}{2}dx$; therefore $\cos x = \frac{1}{2}$; therefore $x = 60°$.

$u = \sin^{-1}x \quad \frac{du}{dx} = \frac{1}{\sqrt{1-x^2}}$. $\quad u = \cos^{-1}x \quad \frac{du}{dx} = -\frac{1}{\sqrt{1-x^2}}$. $\quad u = \tan^{-1}x \quad \frac{du}{dx} = \frac{1}{1+x^2}$.

$u = \sin^{-1}x \quad \frac{du}{dx} = \frac{1}{x\sqrt{x^2-1}}$. $\quad u = \cot^{-1}x \quad \frac{du}{dx} = -\frac{1}{1+x^2}$. $\quad u = \operatorname{cosec}^{-1}x \quad \frac{du}{dx} = -\frac{1}{x\sqrt{x^2-1}}$.

$u = \operatorname{versin}^{-1}x \quad \frac{du}{dx} = \frac{1}{\sqrt{2x-x^2}}$.

$u = \sin^{-1}\frac{x}{a} \quad \frac{du}{dx} = \frac{1}{\sqrt{a^2-x^2}}$. $\quad u = \cos^{-1}\frac{x}{a} \quad \frac{du}{dx} = -\frac{1}{\sqrt{a^2-x^2}}$. $\quad u = \tan^{-1}\frac{x}{a} \quad \frac{du}{dx} = \frac{a}{\sqrt{a^2-x^2}}$.

$u = \sin^{-1}z \quad \frac{du}{dx} = \frac{\frac{dz}{dx}}{\sqrt{1-z^2}}$,

and so on.

Exponential and Logarithmic Functions.

$u = a^x \quad \frac{du}{dx} = \mathrm{A}a^x$, where $\mathrm{A} = \log_e a$, $\qquad u = e^x \quad \frac{du}{dx} = e^x$,

$u = \log_a x \quad \frac{du}{dx} = \frac{1}{\mathrm{A}} \cdot \frac{1}{x}$, $\qquad u = \log_e x \quad \frac{du}{dx} = \frac{1}{x}$,

or the differential coefficient of the logarithm of a function equals the differential coefficient of the function divided by the function itself.

$u = \log_a z \quad \frac{du}{dx} = \frac{1}{\mathrm{A}} \cdot \frac{1}{z} \cdot \frac{dz}{dx}$ $\qquad u = \frac{e^x - e^{-x}}{e^x + e^{-x}} \quad \frac{du}{dx} = \frac{4}{(e^x + e^{-x})^2}$.

$u = x^x \quad \frac{du}{dx} = x^x(1 + \log_e x)$. $\qquad u = x^{\frac{1}{x}} \quad \frac{du}{dx} = \frac{x^{\frac{1}{x}}}{x^2}\log_e\left(\frac{e}{x}\right)$.

Maxima and Minima.

To find the maximum or minimum value of x in an expression differentiate and equate to zero.

EXAMPLE 1.—If $u = x(a - x)$, to find the value of x which makes $x(a - x)$ a maximum.

$$u = x(a-x) = ax - x^2; \quad \frac{du}{dx} = a - 2x = 0 \text{ at a maximum;}$$

therefore

$$a = 2x, \quad \text{or } x = \frac{a}{2}.$$

EXAMPLE 2.—To determine the proportions of a beam of rectangular section which will give the greatest *moment of resistance*.

Let b = breadth of beam, x = depth of beam.

Put $b + x = n$, or, $b = n - x$.

The moment of resistance, u, of the beam is

$$u = bx^2,$$
$$u = (n - x)x^2 = nx^2 - x^3;$$

$$u = bx^2,$$
$$u = (h - x)x^2 = nx^2 - x^3;$$

to obtain the value of x, which makes u a minimum, we have

$$\frac{du}{dx} = 2nx - 3x^2 = 0; \text{ therefore } 2n = 3x;$$

or, since $n = b + x$, therefore $2b + 2x = 3x$;

that is $2b = x$, or, $b = \frac{x}{2}$.

If it is not known whether the expression has a maximum or a minimum, to find whether $u = f(x)$ contains any maxima or minima, put $\frac{du}{dx} = 0$, substitute the values of x thus found in $\frac{d^2u}{dx^2}$; if the result be positive, there are minima; if negative, maxima.

Functions of Two Variables.

$$u = x^m y^n \qquad \frac{du}{dx} = x^{m-1}y^{n-1}(mydx + nzdy).$$

Curves.

Differential Coefficient of Area of Curve.

$$\frac{dA}{dx} = y.$$

Differential Coefficient of Length of Curve.

$$\frac{ds}{dx} = \sqrt{1 + \frac{dy^2}{dx^2}}.$$

Differential Coefficient of Length of Tangent to any Curve.

$$\frac{dt}{dx} = y\sqrt{1 + \frac{dx^2}{dy^2}}.$$

Differential Coefficient of Surface of Solid.

$$\frac{dS}{dx} = 2\pi y\sqrt{1 + \frac{dy^2}{dx^2}} = 2\pi y\frac{ds}{dx}.$$

INTEGRAL CALCULUS.

General Formulæ.

Integral of a Simple Function.

$$\int ax^m dx = \frac{a}{m+1} \cdot x^{m+1} + C. \qquad \int ax^{-1} = a \log_e x + C.$$

$$\int \frac{dz}{\frac{dx}{x^z}} = \int \frac{dz}{dx} \cdot x^{-z} = \log z + C,$$

or, if there be a fraction in which the numerator is the derivative of the denominator, the integral is the logarithm of the denominator.

$$\int \left\{ \frac{dp}{dx} + \frac{dq}{dx} + \frac{dr}{dx} + \text{\&c.} \right\} = \int \frac{d}{dx}(p + q + r + \text{\&c.})dx = p + q + r + \text{\&c.},$$

or, the integral of the sum of any number of differential coefficients = sum of the integrals of each differential coefficient.

$$\int z^m dx \cdot \frac{dz}{dx} = \frac{z^{m+1}}{m+1} + C,$$

or, increase the index by unity, divide by the index so increased, and by the differential coefficient of the quantity under the index.

$$\int \frac{dx}{a + bx^2} = \frac{1}{\sqrt{ab}} \tan^{-1}\left(x\sqrt{\frac{b}{a}}\right). \qquad \int \frac{x}{\sqrt{a^2 - x^2}} dx = -\sqrt{a^2 - x^2}.$$

$$\int \frac{dx}{\sqrt{a^2 - x^2}} = \sin^{-1}\frac{x}{a}. \qquad \int \frac{-dx}{\sqrt{a^2 - x^2}} = \cos^{-1}\frac{x}{a}.$$

$$\int \frac{adx}{x^2 - a^2} = \frac{1}{2}\log_e\left(\frac{x-a}{x+a}\right). \qquad \int a^x dx = \frac{a^x}{\log_e a}. \qquad \int \frac{dx}{x - x^2} = \log_e \frac{x}{1-x}.$$

$$\int e^{ax}dx = \frac{e^{ax}}{a}. \qquad \int \frac{d\theta}{\sin\theta} = \log_e \tan\frac{\theta}{2}. \qquad \int \frac{d\theta}{\cos\theta} = \log_e \tan\left\{\frac{\pi}{4} + \frac{\theta}{2}\right\}.$$

$$\int \frac{d\theta}{\sin\theta\cos\theta} = \log\tan\theta. \qquad \int \frac{dx}{1+x+x^2} = \frac{2}{\sqrt{3}}\tan^{-1}\left\{\frac{2x+1}{\sqrt{3}}\right\} \text{ (a useful integral).}$$

$$\int \frac{4dx}{(x+4)^2} = \frac{-4}{x+4}. \qquad \int \frac{dx}{(x+2)^2} = \frac{-1}{x+2}. \qquad \int \frac{2xdx}{(x^2+1)(x^2+3)} = \log_e \sqrt{\frac{x^2+1}{x^2+3}}.$$

$$\int \frac{dx}{1+3x+2x^2} = \log_e \frac{2x+1}{x+1}. \qquad \int \frac{dx}{x(x^3+1)} = \log \sqrt[3]{\frac{x^3}{x^3+1}}.$$

$$\int \frac{dx}{x\sqrt{x+a}} = \frac{2}{\sqrt{a}}\log_e \frac{\sqrt{x}}{\sqrt{a+x}+\sqrt{a}}. \qquad \int \frac{dx}{\sqrt{1+x-x^2}} = \sin^{-1}\frac{2x-1}{\sqrt{5}}.$$

$$\int \frac{dx}{x\sqrt{1+x+x^2}} = \log_e \frac{2+x-2\sqrt{1+x+x^2}}{-3x}. \qquad \int \frac{x^2dx}{\sqrt{a^2-x^2}} = \frac{a^2}{a}\sin^{-1}\frac{x}{a} - \left(a+\frac{x}{2}\right)\sqrt{a^2-x^2}.$$

$$\int \frac{x^2dx}{\sqrt{1-x^2}} = \frac{1}{2}\sin^{-1}x - \frac{x}{2}\sqrt{1-x^2}. \qquad \int e^x x dx = e^x x - e^x. \qquad \int e^{-x} x dx = -e^{-x}x - e^{-x}.$$

$$\int e^x x^2 dx = e^x x^2 - 2\int e^x x dx. \qquad \int e^{-x} x^2 dx = -e^{-x}x^2 + 2\int e^{-x} x dx.$$

$$\int \frac{dx}{\sqrt{1-x^2}} = \sin^{-1}x. \qquad \int \frac{-dx}{\sqrt{1-x^2}} = \cos^{-1}x.$$

$$\text{Length of curve} = \int \sqrt{1+\frac{dy^2}{dx^2}}\,dx. \qquad \text{Area of curve} = \int y dx.$$

$$\text{Surface of solid body} = 2\pi\int y\sqrt{1+\frac{dy^2}{dx^2}}\,dx. \qquad \text{Volume of solid body} = \pi\int y^2 dx.$$

Examples of Use of Integral Calculus.

Example 1.—To determine the moment of friction of the end of the screw of a screw-jack.

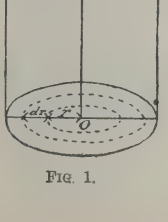

Fig. 1.

Let Q be the pressure along the axis of the screw, μ the coefficient of friction, and ρ the radius of the pivot (say in inches), then pressure per square inch will be $\frac{Q}{\pi\rho^2}$, and consequently $\frac{\mu Q}{\pi\rho^2}$ will be the friction per square inch; hence, if we consider a small ring enclosed between two circles whose radii are respectively r and $r+dr$, its area will ultimately equal $2\pi r dr$, and the pressure on it will equal $\frac{2\mu Q}{\rho^2}rdr$. Now the friction at any point of this ring acts in a direction perpendicular to the radius at that point, and hence the sum of the moments of the friction on this ring with respect to the axis will ultimately equal

$$\frac{2\mu Q}{\rho^2}r^2dr.$$

To obtain the whole friction, u, we must integrate this expression between the limits $r = 0$ and $r = \rho$, that is

$$u = \int_{\rho}^{0}\frac{2\mu Q}{\rho^2}r^2dr, \quad \text{or,} \quad u = \frac{2\mu Q}{\rho^2}\int_{\rho}^{o} r^2dr = \frac{2\mu Q}{\rho^2}\left(\frac{\rho^3}{3}\right) = \frac{2}{3}\rho\mu Q.$$

GEOMETRY.

CONSTRUCTIONS.

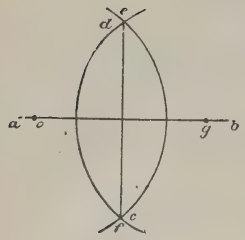

FIG. 2.

To divide a given line, *ab*, into two equal parts.

From its ends *a* and *b* as centres, and with any radius greater than one-half of *ab*, describe the arcs *c* and *d*, and join *ef*. If the line *ab* is very long, first lay off equal distances, *ao* and *bg*, each way from the ends, so as to approach conveniently near to each other; and then proceed as if *og* were the line to be divided. Or measure *ab* by a scale, and thus ascertain its centre.

To divide a given line, *mn*, into any given number of equal parts.

From *m* and *n* draw any two parallel lines, *mo* and *na*, to an indefinite distance, and on them, from *m* and *n*, step off the required number of equal parts of any convenient length; finally, join the corresponding points thus stepped off. Or only one line, as *mo*, may be drawn and stepped off, as to *s*; then join *sn*; and draw the other short lines parallel to it.

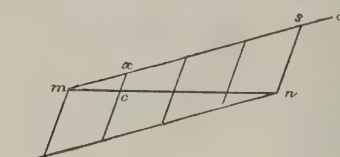

FIG. 3.

To divide a given line, *mn*, into two parts which shall have a given proportion to each other.

This is done on the same principle as the last; thus, let the proportion be as 1 to 3. First draw any line, *mo*, and with any convenient opening of the dividers make *mx* equal to one step, and *xs* equal to three steps. Join *sn*; and parallel to it draw *xc*. Then *mc* is to *cn* as 1 is to 3.

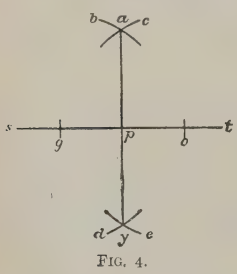

FIG. 4.

From any given point, *p*, on a line, *st*, to draw a perpendicular, *pa*.

From *p*, with any convenient opening of the dividers, step off the equals *po*, *pg*. From *o* and *g* as centres, with any opening greater than half *og*, describe the two short arcs *b* and *c*, and join *ap*. Or, still better, describe four arcs, and join *ay*.

Or from *p* with any convenient scale describe two short arcs, *g* and *c*, one of them with a radius 3, and the other with a radius 4. Then from *g*, with a radius 5, describe the arc *b*. Join *pa*.

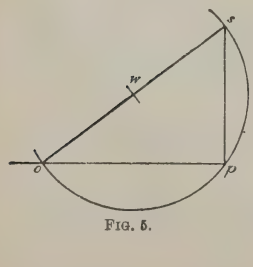

FIG. 5.

If the point p *is at one end of the line, or very near it*, extend the line, if possible, and proceed as above. But if this cannot be done, then from any convenient point, *w*, open the dividers to *p*, and describe the semicircle *spo*; through *ow* draw *ows*; join *ps*.

Or use the foregoing process with radii 3, 4, and 5.

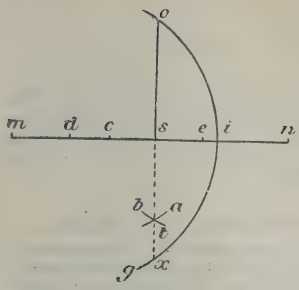

FIG. 6.

From a given point, *o*, to let fall a perpendicular, *os*, to a given line, *mn*.

From *o* measure to the line *mn* any two equal distances, *oc*, *oe*; and from *c* and *e* as centres, with any opening greater than half of *ce*, describe the two arcs *a* and *b*; join *ot*. Or from any point, as *d* on the line, open the dividers to *o*, and describe the arc *og*; make *ix* equal to *io*, and join *ox*.

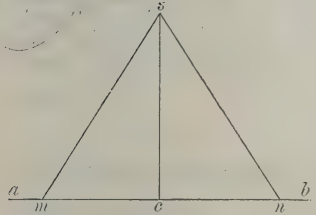

FIG. 7.

If the line ab *is on the ground*, and a perpendicular is required to be drawn from *c*, first measure off any two equal distances, *cm*, *cn*. At *m* and *n* hold the ends of a piece of string, tape-line, or chain, *msn*; then tighten out the string, &c., as shown by *msn*, *s* being its centre. Then will *sc* be the required perpendicular.

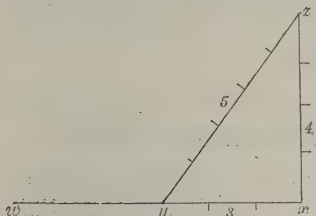

FIG. 8.

If the perpendicular, xz, *is to be drawn from the end of the line* wx, first measure *xy* upon the line, and equal to three feet; then, holding the end of a tape-line at *x*, and its nine-feet mark at *y*, hold the four-feet mark at *z*, keeping *zx* and *zy* equally stretched. Then *zx* will be the required perpendicular, because 3, 4, and 5 make the sides of a right-angled triangle. Instead of 3, 4, and 5, any multiples of those numbers may be used, such as 6, 8, and 10, or 9, 12, 15, &c.; also, instead of feet we may use yards, chains, &c.

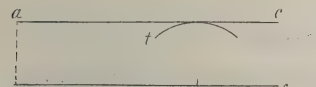

FIG. 9.

Through a given point, *a*, to draw a line, *ac*, parallel to another line, *ef*.

With the perpendicular distance *ae*, from any point, *n*, on *ef*, describe an arc, *t*; draw *ac* just touching the arc.

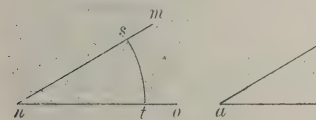

FIG. 10.

At any point, *a*, in a line *ab*, to make an angle, *cab*, equal to a given angle, *mno*.

From *n* and *a*, with any convenient radius, describe the arcs *st*, *de*; measure *st*, and make *de* equal to it; through *ad* draw *ac*.

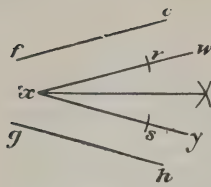

FIG. 11.

Bisection of an Angle.

Let *wxy* be the angle

From *x* set off any two equal distances, *xr*, *xs*. From *r* and *s*, with any radius, describe two arcs intersecting, as at *o*, and join *ox*. If the two sides of the angle do not meet, as *cf* and *gh*, either first extend them until they do meet, or else draw lines, *xw* and *xy*, parallel to them, and at equal distances from them, so as to meet; then proceed as before.

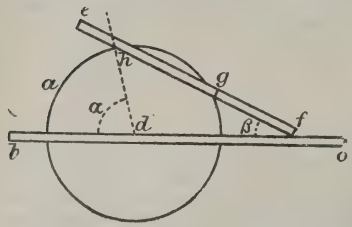

FIG. 11A.

Trisection of an Angle.

a is a circle, of which *d* is the centre. *bc* is a ruler whose upper edge touches the centre *d*. *a* is the angle whose trisection is required. *ef* is a second ruler which has a mark at *g*, the distance *gf* being equal to the radius of the circle. At the point *h* a pin is inserted, on which the ruler *ef* can slide. To obtain a trisection of the angle *a*, slide the corner of the ruler *ef* along *bc* until the mark *g* comes on the circumference of the circle. Then the angle β will be equal to $\alpha \div 3$.

(*H. R. Kempe.*)

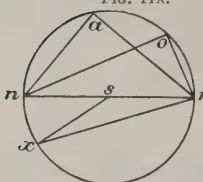

FIG. 12.

Angles at the circumference of a Semicircle.

All angles, as *nam*, *nom*, at the circumference of a semicircle, and standing on its diameter, *nm*, are right angles; or, as it is usually expressed, *all angles in a semicircle are right angles.* An angle, *nsx*, at the centre of a circle is twice as great as an angle, *nmx*, at the circumference, when both stand upon the same arc, *nx*.

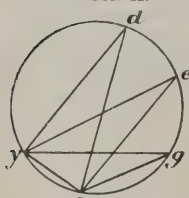

FIG. 13.

Angles at the circumference of a Circle.

All angles, as *ydp*, *yep*, *ygp*, at the circumference of a circle, and standing upon the same arc, as *yp*, are equal to each other; or, as usually expressed, *all angles in the same segment of a circle are equal.*

Angles in a Parallelogram.

A parallelogram is any four-sided straight-lined figure whose opposite sides are equal, as *abcd*; or a square, &c. Any line drawn across a parallelogram between two opposite angles is called a *diagonal*, as *ac* or *bd*. A diagonal divides a parallelogram into two equal parts, as does also any line, *mn*, drawn through the centre of either diagonal; and, moreover, the line *mn* itself is divided into two equal parts by the diagonal. Two diagonals bisect each other; they also divide the parallelogram into four triangles of equal area. The sum of the two angles at the ends of any one side is=180°; thus, $dab + abc = abc + bcd = 180°$; and the sum of the four angles, *dab*, *abc*, *bcd*, *cda* = 360°.

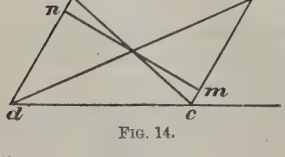

FIG. 14.

The sum of the squares of the four sides is equal to the sum of the squares of the two diagonals.

To construct an Ellipse.

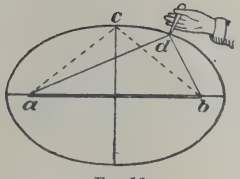

FIG. 15.

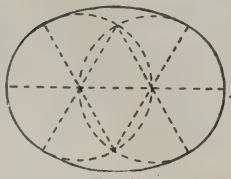

FIG. 16.

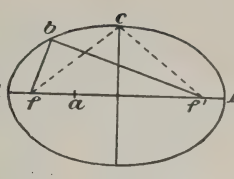

FIG. 17.

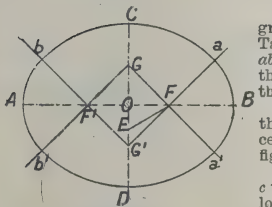

FIG. 18.

(1.) Having given the two axes, fig. 15, set off from c half the great axis at a and b, which are the two foci in the ellipse. Take an endless string as long as the three sides in the triangle abc, fix two pins or nails in the foci, one in a and one in b, lay the string round a and b, stretch it with a pencil, d, which then will describe the desired ellipse.

(2.) Divide the long axis, fig. 16, into three equal parts, draw the two circles, and where they intersect one another are the centres for the tangent arcs of the ellipse, as shown by the figure.

(3.) Given the two axes, fig. 17, set off half the long axis from c to f f', which will be the two foci in the ellipse. Divide the long axis into any number of parts, say a to be a division point. Take Aa as radius and f as centre, and describe a circle arc about b; take aB as radius and f as centre, describe another circle arc about b; then the intersection b is a point in the ellipse, and so the whole ellipse can be constructed.

(4.) Let A B, C D, fig. 18, be the major and minor axes of an ellipse with centre at O.

1. With distance A O cut off C E on C D. 2. From E at 60° with C E, draw E F. 3. From F at 45°, draw diagonal lines.

Then from G as a centre strike the arc a' D b', and from G' strike the arc a C b; also from F strike the arc a A a', and from F' strike the arc b B b'; then the figure will be very approximately an ellipse provided the ratio of the major to the minor axis is not greater than 3·2.

(*D. A. Coates*, '*The Engineer*,' *October* 13, 1911.)

To construct a Cycloid.

FIG. 19

On the line AB lay off any points, 1, 2, 3, 4, &c.; draw perpendicular lines at each point, and on each describe circles equal to the generating circle.

On the circum. of the circle at } 1 lay off 1.1′=A.1.
" " 2 lay off 2.2′=A.2.
" " 3 lay off 3.3′=A.3.

and so on; the points 1′, 2′, 3′, 4′, 5′, are points of the curve.

To construct a Screw Helix.

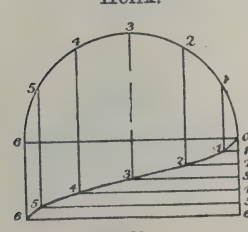

FIG. 20.

In a given Circle to inscribe any Regular Polygon.

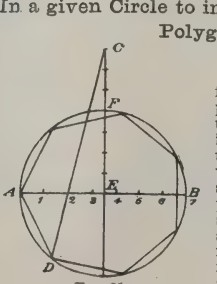

FIG. 21.

Draw the diameter, AB; from E, the centre, erect the perpendicular, EFC, cutting the circle at F. Divide EF into four equal parts, and set three parts from F to C. Divide the diameter, AB, into as many equal parts as the polygon is required to have sides. From C, through the second division in the diameter, draw CD. Join AD; it will be the side of the polygon required.

(*H. R. Kempe.*)

CONIC SECTIONS.

A *Cone* is a figure described by the revolution of a right-angled triangle about one of its legs, or it is a solid having a circle for its base, and terminated in a vertex.

Conic Sections are the figures made by a plane cutting a cone.

The *Axis* is the line about which the triangle revolves.

The *Base* is the circle which is described by the revolving base of the triangle.

If a cone is cut by a plane through the vertex and base, the section will be a triangle.

If a cone is cut by a plane parallel to its base, the section will be a circle.

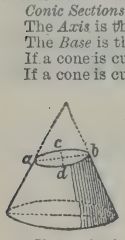

FIG. 76.

An *Ellipse* is a figure generated by an oblique plane cutting a cone above its base.

The *transverse axis* or diameter is the longest right line that can be drawn in it, as *ab*, fig. 76.

The *conjugate axis* or diameter is a line drawn through the centre of the ellipse perpendicular to the transverse axis, as *cd*.

A *Parabola* is a figure generated by a plane cutting a cone parallel to its side, as *abc*, fig. 77.

The *axis* is a right line drawn from the vertex to the middle of the base, as *bo*.

A parabola has no conjugate diameter.

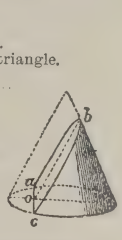

FIG. 77.

An *Hyperbola* is a figure generated by a plane cutting a cone at any angle with the base greater than that of the side of the cone, as *abc*, fig. 78.

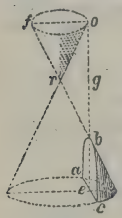

FIG. 78.

The *transverse axis* or diameter, *ob*, is that part of the axis, *eb*, which, if continued, as at *o*, would join an opposite cone, *ofr*.

The *conjugate axis* or diameter is a right line drawn through the centre, *g*, of the transverse axis, and perpendicular to it.

The straight line through the *foci* is the indefinite transverse axis; that part of it between the vertices of the curves, as *ob*, is the definite transverse axis. Its middle point, *g*, is the centre of the curve.

The *eccentricity* of a hyperbola is the ratio obtained by dividing the distance from the centre to either *focus* by the semi-transverse axis.

The *asymptotes* of a hyperbola are two right lines to which the curve continually approaches, touches at an infinite distance, but does not pass; they are prolongations of the diagonals of the rectangle constructed on the extremes of the axes.

Two hyperbolas are *conjugate* when the transverse axis of the one is the conjugate of the other, and *vice versâ*.

General Definitions.

An *Ordinate* is a right line from any point of a curve to either of the diameters, *ae* and *do*, fig. 79; *ab* and *df* are double ordinates.

An *Abscissa* is that part of the diameter which is contained between the vertex and an ordinate, as *ce*, *go*.

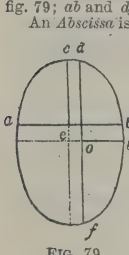

FIG. 79.

The *parameter of any diameter* is equal to four times the distance from the *focus* to the vertex of the curve; the parameter of the axis is the least possible, and is termed the parameter of the curve.

The *parameter of the curve of a conic section* is equal to the chord of the curve drawn through the *focus* perpendicular to the axis.

The *parameter of the transverse axis* is the least, and is termed the parameter of the curve.

The *parameter of a conic section* and the *foci* are sufficient elements for the construction of the curve.

In the *Parabola*, the parameter of any diameter is a third proportional to the abscissa and ordinate of any point of the curve, the abscissa and ordinate being referred to that diameter and the tangent at its vertex.

In the *Ellipse* and *Hyperbola* the parameter of any diameter is a third proportional to the diameter and its conjugate.

A *focus* is a point on the principal axis where the double ordinate to the axis, through the point, is equal to the parameter, as *ef*, fig. 80. It may be determined arithmetically thus: Divide the square of the ordinate by four times the abscissa, and the quotient will give the focal distance, *gs*, fig. 80.

A *Conoid* is a warped surface generated by a right line being moved in such a manner that it will touch a straight line and curve, and continue parallel to a given plane. The straight line and curve are called *directrices*, the plane a plane *directrix*, and the moving line the *generatrix*.

The *Directrix* of a conic section is a straight line such that the ratio obtained by dividing the distance from any point of the curve to it by the distance from the same point to the focus shall be constant. It is always perpendicular to the principal axis.

THE ELLIPSE.

To compute the Parameter of an Ellipse, the Transverse and Conjugate Diameters being given (fig. 80).

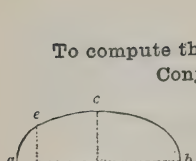

FIG. 80.

RULE.—Divide the square of the conjugate diameter by the transverse diameter, and the quotient is equal to the parameter.

EXAMPLE.—In the ellipse (fig. 80), the transverse and conjugate diameters, *gb*, *ck*, are 30 and 20.

Then $\frac{20 \times 20}{30} = 13{\cdot}333 = \textit{parameter.}$

The parameter of the curve = *ef*, a double ordinate passing through the focus, *s*.

To compute the Ordinate of an Ellipse, the Transverse and Conjugate Diameters and the Abscissa being given (fig. 81).

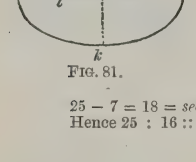

FIG. 81.

RULE.—As the transverse diameter is to the conjugate, so is the square root of the product of the abscissæ to the ordinate which divides them.

Or, $\frac{d}{D}\sqrt{a'(D-a')} = y$, D *representing the transverse diameter, d the conjugate, a' the lesser abscissa, and y the ordinate.*

EXAMPLE.—The transverse diameter, *gb*, of an ellipse (fig. 81) is 25 (D); the conjugate, *ck*, is 16 (*d*); and the abscissa, *gi*, 7 (*a'*); what is the length, *y*, of the ordinate, *ie*?

$25 - 7 = 18 = \textit{second abscissa}$; $\sqrt{7 \times 18} = 11{\cdot}225 = \textit{square root of the abscissæ.}$
Hence 25 : 16 :: 11·225 : 7·184 *inches = length of the ordinate.*

To compute the Abscissæ of an Ellipse, the Transverse and Conjugate Diameters and the Ordinate being given (fig. 81).

RULE.—As the conjugate diameter is to the transverse, so is the square root of the difference of the squares of the ordinate and semi-conjugate to the distance between the ordinate and centre; and this distance being added to, or subtracted from, the semi-transverse, will give the abscissæ required.

Or

$$\frac{D}{d}\sqrt{\left(\frac{d}{2}\right)^2 - y^2} = x, \text{ and } \begin{cases} D \div 2 + x = a, \\ D \div 2 - x = a', \end{cases} \textit{ x representing the distance obtained, and a, a', the greater and lesser abscissæ.}$$

EXAMPLE.—The transverse diameter, *gb*, of an ellipse (fig. 81) is 25 (D); the conjugate, *ck*, 16 (*d*); and the ordinate, *ie*, 7·184 (*y*); what are the abscissæ, *bi*, *gi*?

$\sqrt{8^2 - 7{\cdot}184^2} = 3{\cdot}519943 = \textit{square root of difference of squares of semi-conjugate and ordinate.}$

Hence, as 16 : 25 :: 3·52 : 5·5 = *distance between ordinate and centre.*

Then $\left.\begin{array}{l} 25 \div 2 = 12{\cdot}5, \text{ and } 12{\cdot}5 + 5{\cdot}5 = 18 = bi, \\ 25 \div 2 = 12{\cdot}5, \text{ and } 12{\cdot}5 - 5{\cdot}5 = \ 7 = gi, \end{array}\right\}$ *abscissæ.*

To compute the Transverse Diameter of an Ellipse, the Conjugate, Ordinate, and Abscissa being given (fig. 81).

RULE.—To or from the semi-conjugate, according as the greater or lesser abscissa is used, add or subtract the square root of the difference of the square of the ordinate and semi-conjugate. Then, as this sum or difference is to the abscissa, so is the conjugate to the transverse.

Or,

$$\frac{ad}{\frac{d}{2} \pm \sqrt{y^2 - \left(\frac{d}{2}\right)^2}} = \text{D}.$$

EXAMPLE.—The conjugate diameter, *ck*, of an ellipse (fig. 81) is 16 (*d*); the ordinate, *ie*, is 7·184 (*y*); and the abscissæ, *bi*, *ig*, are 18 (*a*) and 7 (*a'*); what is the length of the transverse diameter (D)?

$(16 \div 2)^2 - 7{\cdot}184^2 = 3{\cdot}52$ = *square root of difference of squares of ordinate and semi-conjugate.*
$16 \div 2 + 3{\cdot}52 : 18 :: 16 : 25$; $16 \div 2 - 3{\cdot}52 : 7 :: 16 : 25$ = *transverse diameter.*

To compute the Conjugate Diameter of an Ellipse, the Transverse Diameter, Ordinate, and Abscissa being given (fig. 81).

RULE.—As the square root of the product of the abscissæ is to the ordinate, so is the transverse diameter to the conjugate.

Or,

$$y\text{D} \div \sqrt{a \times a'} = d.$$

EXAMPLE.—The transverse diameter, *gb*, of an ellipse (fig. 81) is 25 (D); the ordinate, *ie*, is 7·184 (*y*); and the abscissæ, *bi* and *ig*, 18 (*a*) and 7 (*a'*); what is the length (*d*) of the conjugate diameter?

$\sqrt{18 \times 7} = 11{\cdot}225$ = *square root of product of abscissæ.*
$11{\cdot}225 : 7{\cdot}184 :: 25 : 16$ = *conjugate diameter.*

To compute the Circumference of an Ellipse (fig. 81).

RULE.—Multiply the square root of half the sum of the squares of the two diameters by 3·1416.

Or,

$$\sqrt{\frac{\text{D}^2 + d^2}{2}} \times 3{\cdot}1416 = \textit{circumference.}$$

EXAMPLE.—The transverse and conjugate diameters, *gb* and *ck*, of an ellipse (fig. 81) are 24 and 20; what is its circumference?

$\frac{24^2 + 20^2}{2} = 488$, and $\sqrt{488} = 22{\cdot}09$ = *square root of half the sum of the squares of the diameters.*

Hence $22{\cdot}09 \times 3{\cdot}1416 = 69{\cdot}398$ = *circumference.*

To compute the Area of an Ellipse (fig. 81).

RULE.—Multiply the diameters together, and the product by ·7854. Or, multiply one diameter by ·7854, and the product by the other.

Or,

$$\text{D} \times d \times {\cdot}7854 = \textit{area.}$$

EXAMPLE.—The transverse diameter of an ellipse, *gb*, fig. 81, is 12 (D), and its conjugate, *ck*, 9 (*d*); what is its area?

$12 \times 9 \times {\cdot}7854 = 84{\cdot}8232$ = *product of diameters and* ·7854 = *area.*

To compute the Area of a Segment of an Ellipse when its Base is parallel to either Axis, as *ein*, fig. 82.

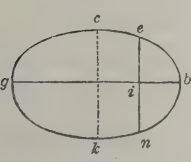

FIG. 82.

Ascertain the segment of the circle described upon the same axis to which the base of the segment is perpendicular. Then, as this axis is to the other axis, so is the circular segment to the elliptical segment.

EXAMPLE.—The axis to which the base of the segment is perpendicular is 50, and the height of the segment, 25. *Also, the area of the segment is one-half of that of a circle of* 50 *diameter*

$$= \frac{1963{\cdot}4954}{2} = 981{\cdot}7477.$$

Hence $50 : 70 :: 981{\cdot}75 : 1374{\cdot}45$ = *area of elliptic segment.*

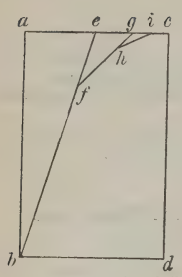

FIG. 83.

THE PARABOLA.

To draw a Parabola, the Base and Height being given (fig. 83).

Required a semi-parabola of which *bd* is an ordinate, the corresponding height being *ab*.

Bisect *ac* and draw *eb*. Make *ef* = one-quarter of *be*. Bisect *ec* and draw *fg*. Make *gh* = one-quarter of *fg* and join *h* to the bisection, *i*, of *gc*. (*C. H. Wingfield.*)

To compute either Ordinate or Abscissa of a Parabola, the other Ordinate and the Abscissæ, or the other Abscissa and the Ordinates, being given (fig. 84).

RULE.—As either abscissa is to the square of its ordinate, so is the other abscissa to the square of its ordinate.

Or,

$$\frac{y^2 \times a'}{a} = y'^2. \qquad \frac{y'^2 \times a}{a'} = y^2.$$

$$\frac{y^2 \times a'}{y'^2} = a. \qquad \frac{y'^2 \times a}{y^2} = a'.$$

Or, as the square root of any abscissa is to its ordinate, so is the square root of any other abscissa to its ordinate. Hence

$$\frac{y \times \sqrt{a'}}{\sqrt{a}} = y'.$$

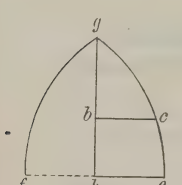

FIG. 84.

EXAMPLE 1.—The abscissa, *gb*, of the parabola, fig. 84, is 9 (*a*) ; its ordinate, *bc*, 6 (*y*) ; what is the ordinate, *ke* (*y'*), the abscissa of which, *gk*, is 16 (*a'*).

9 : 6^2 :: 16 : 64, and $\sqrt{64} = 8 = \textit{length of ordinate.}$

Or, $\sqrt{9} : 6 :: \sqrt{16} : 8 = \textit{ordinate.}$

EXAMPLE 2.—The abscissæ of a parabola are 9 (*a'*) and 16 (*a*), and their corresponding ordinates 6 (*y'*) and 8 (*y*) ; any three of these being taken, it is required to find the fourth.

$$\sqrt{\frac{6^2 \times 16}{9}} = 8 = \textit{ordinate.} \qquad \sqrt{\frac{8^2 \times 9}{16}} = 6 = \textit{ordinate.}$$

$$\frac{6^2 \times 16}{8^2} = 9 = \textit{lesser abscissa.} \qquad \frac{8^2 \times 9}{6^2} = 16 = \textit{abscissa.}$$

To compute the Length of the Curve of a Parabola cut off by a Double Ordinate (fig. 84).

RULE.—To the square of the ordinate add $\frac{4}{3}$ of the square of the abscissa, and the square root of this sum, multiplied by two, will give the length of the curve nearly.

Or,

$$\sqrt{\left(y^2 + \frac{4a^2}{3}\right)}2 = \textit{length of curve.}$$

EXAMPLE.—The ordinate, *ke*, fig. 84, is 8 (*y*), and its abscissa, *gk*, 16 (*a*) ; what is the length of the curve *fge* ?

$$8^2 + \frac{4 \times 16^2}{3} = 405{\cdot}333 = \textit{sum of square of the ordinate and } \tfrac{4}{3} \textit{ of the square of the abscissa, and}$$

$\sqrt{405{\cdot}333} = 20{\cdot}133$, which $\times\ 2 = 40{\cdot}267 = \textit{length.}$

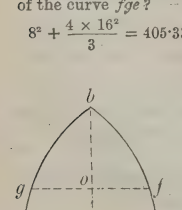

FIG. 85.

To compute the Area of a Parabola (fig. 85).

RULE.—Multiply the base (*a*) by the height (*h*), and take $\frac{2}{3}$ of the product.

Or,

$$\frac{2}{3}a \times h = \textit{area.}$$

EXAMPLE.—What is the area of the parabola *abc*, fig. 85, the height, *be*, being 16 (*h*), and the base, or double ordinate, *ac*, 16 (*a*) ?

$16 \times 16 = 256 = \textit{product of base and height, and } \frac{2}{3} \textit{ of } 256 = 170{\cdot}667 = \textit{area.}$

To compute the Area of a Segment of a Parabola (fig. 85).

RULE.—Multiply the difference of the cubes of the two ends of the segment, *ac*, *qf*, by twice its altitude, *eo*, and divide the product by three times the difference of the squares of the ends.

Or,

$$\frac{(l^3 - l'^3)2h}{(l^2 - l'^2)3} = \textit{area, } l \textit{ and } l' \textit{ representing the lengths of the base and lesser ends.}$$

EXAMPLE 1.—The ends of a segment of a parabola, *ac* and *qf*, fig. 85, are 10 (*l*) and 6 (*l'*), and the height, *eo*, is 10 (*h*); what is its area?

$(10^3 - 6^3)(2 \times 10) = 15680 =$ *difference of cubes of the ends* × *twice the height.*
$15680 \div (10^2 - 6^2)3 = 81{\cdot}667 =$ *preceding product* ÷ 3 *times the difference of the squares of the ends* = *area.*

Any parabolic segment is equal to a parabola of the same altitude, the base of which is equal to the base of the segment, increased by a third proportional to the sum of the two ends and the lesser end.

EXAMPLE 2.—In Example 1 the base and end are 10 and 6.

Then $10 + 6 : 6 :: 6 : 2{\cdot}25 =$ *third proportional to the sum of the two ends and the lesser end.*
Hence $10 + 2{\cdot}25 = 12{\cdot}25 =$ *sum of length of base of parabola and third proportional; and the area, the height being* 10, $= 81{\cdot}667$.

THE HYPERBOLA.

To compute the Ordinate of an Hyperbola, the Transverse and Conjugate Diameters and the Abscissæ being given (fig. 86).

RULE.—As the transverse diameter is to the conjugate, so is the square root of the product of the abscissæ to the ordinate required.

Or,

$$\frac{d \times \sqrt{a \times a'}}{\mathrm{D}} = \textit{ordinate.}$$

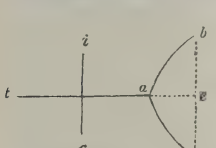

FIG. 86.

EXAMPLE.—The hyperbola *abc*, fig. 86, has a transverse diameter, *at*, of 120 (D); a conjugate, *if*, of 72 (*d*); and the abscissa *ae* is 40 (*a*); what is the length of the ordinate *ec*?

$40 + 120 = a' =$ *sum of lesser abscissa and axis = greater abscissa.*

$120 : 72 :: \sqrt{40 \times 160} : 48 =$ *ordinate.*

In hyperbolas the lesser abscissa, added to the axis (the transverse diameter), gives the greater.

The difference of two lines drawn from the *foci* of any hyperbola to any point in the curve is equal to its transverse diameter.

To compute the Abscissa of an Hyperbola, the Transverse and Conjugate Diameters and the Ordinate being given (fig. 86).

RULE.—As the conjugate diameter is to the transverse, so is the square root of the sum of the squares of the ordinate and semi-conjugate to the distance between the ordinate and the centre, or half the sum of the abscissæ. Then the sum of this distance and the semi-transverse will give the greater abscissa, and their difference the lesser abscissa.

Or,

$$\frac{\mathrm{D}\sqrt{y^2 + (d \div 2)^2}}{d} = \frac{a + a'}{2} = \textit{half the sum of the abscissæ.}$$

$$\frac{a + a'}{2} + \frac{t}{2} = a, \quad \text{and} \quad \frac{a + a'}{2} - \frac{t}{2} = a'.$$

EXAMPLE.—The transverse diameter, *at*, of a hyperbola (fig. 86) is 120 (D); the conjugate, *if*, 72 (*d*); and the ordinate, *ec*, 48 (*y*); what are the lengths of the abscissæ, *te* and *ae*?

$72 : 120 :: \sqrt{48^2 + (72 \div 2)^2} = 60 : 100 =$ *half the sum of the abscissæ.*
$100 + (120 \div 2) = 160 =$ *above sum added to the semi-transverse = the greater abscissa*; and
$100 - (120 \div 2) = 40 =$ *above sum subtracted from the semi-transverse = the lesser abscissa.*

To compute the Conjugate Diameter of an Hyperbola, the Transverse Diameter, the Abscissæ, and Ordinate being given (fig. 86).

RULE.—As the square root of the product of the abscissæ is to the ordinate, so is the transverse diameter to the conjugate.

Or,

$$\frac{y\mathrm{D}}{\sqrt{a \times a'}} = \textit{conjugate diameter.}$$

EXAMPLE.—The transverse diameter, *at*, of a hyperbola (fig. 86) is 120 (D); the ordinate, *ec*, 8 (*y*); and the abscissæ, *te* and *ae*, 160 (*a*) and 40 (*a'*); what is the length of the conjugate, *if*?

$$\sqrt{40 \times 160} = 80 \;:\; 48 \;::\; 120 \;:\; 72 = \textit{conjugate.}$$

To compute the Transverse Diameter of an Hyperbola, the Conjugate, the Ordinate, and an Abscissa being given (fig. 86).

RULE.—Add the square of the ordinate to the square of the semi-conjugate, and extract the square root of their sum.

Take the sum or difference of the semi-conjugate and this root, according as the greater or lesser abscissa is used.* Then, as the square of the ordinate is to the product of the abscissa and conjugate, so is the sum or difference above ascertained to the transverse diameter required.

Or,

$$a \text{ or } a' \times d \times \left\{ \sqrt{y^2 + (d \div 2)^2} \pm (d \div 2) \right\} \div y^2 = \textit{transverse diameter.}$$

EXAMPLE.—The conjugate diameter, *if*, of a hyperbola (fig. 86) is 72 (*d*); the ordinate *ec*, 48 (*y*); and the lesser abscissa, *ae*, 40 (*a'*); what is the length of the transverse diameter, *at*?

$\sqrt{48^2 + (72 \div 2)^2} = 60 =$ *square root of the squares of the ordinate and semi-conjugate.*
$60 + (72 \div 2) = 96 =$ *sum of above root and the semi-conjugate* (the lesser abscissa being used).
$40 \times 72 = 2880 =$ *product of abscissa and conjugate.*
$48^2 : 2880 :: 96 : 120 =$ *transverse diameter.*

To compute the Length of any Arc of an Hyperbola, commencing at the Vertex (fig. 87).

RULE.—To 19 times the transverse diameter add 21 times the parameter of the axis, and multiply the sum by the quotient of the lesser abscissa divided by the transverse diameter.

To 9 times the transverse diameter add 21 times the parameter, and multiply the sum by the quotient of the lesser abscissa divided by the transverse diameter.

To each of the products thus ascertained add 15 times the parameter, and divide the former by the latter; then this quotient, being multiplied by the ordinate, will give the length of the arc nearly.

Or,

$$\frac{(19\mathrm{D} + 21p)\,\frac{a}{\mathrm{D}} + 15p}{(9\mathrm{D} + 21p)\,\frac{a}{\mathrm{D}} + 15p} \times y = \textit{arc nearly.}$$

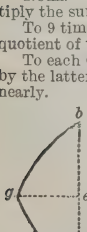

FIG. 87.

EXAMPLE.—In the hyperbola *gbc*, fig. 87, the transverse diameter is 120 (D), the conjugate 80 (*d*), the ordinate, *ec*, 48 (*y*), and the lesser abscissa, *ge*, 40 (*a'*); what is the length of the arc *gb*?

$$120 : 80 :: 80 : 53{\cdot}3333 = \textit{parameter.}$$

$$\left\{(19 \times 120) + (21 \times 53{\cdot}3333)\right\} \times \frac{40}{120} = 1133{\cdot}3333 = \textit{product of the sum of 19 times the transverse and 21 times the parameter, by the quotient of the lesser abscissa and the transverse.}$$

* When the greater abscissa is used, the difference is taken, and *vice versâ*.

$(9 \times 120) + (21 \times 53{\cdot}3333) \times \frac{40}{120} = 733{\cdot}3333 =$ *product of the sum of* 9 *times the transverse and* 21 *times the parameter, by the quotient of the lesser abscissa and transverse.*

$1133{\cdot}333 + (15 \times 53{\cdot}333) \div (733{\cdot}333 + (15 \times 53{\cdot}333)) = 1{\cdot}2609 =$ *quotient of former product and* 15 *times the parameter ÷ latter product and* 15 *times the parameter.*

$1{\cdot}2609 \times 48 = 60{\cdot}5232 =$ *above quotient × the ordinate = length.*

As the transverse diameter is to the conjugate, so is the conjugate to the parameter.

To compute the Area of an Hyperbola, the Transverse, Conjugate, and Lesser Abscissa being given (fig. 87).

RULE.—To the product of the transverse diameter and lesser abscissa add $\frac{4}{7}$ of the square of this abscissa, and multiply the square root of the sum by 21.

Add 4 times the square root of the product of the transverse diameter and lesser abscissa to the product last ascertained, and divide the sum by 75.

Divide 4 times the product of the conjugate diameter and lesser abscissa by the transverse diameter, and this last quotient, multiplied by the former, will give the area nearly.

Or,

$$\frac{21\sqrt{\mathrm{D}a' + \frac{5}{7}a'^2} + 4\sqrt{\mathrm{D}a'}}{75} \times \frac{4da'}{\mathrm{D}} = area.$$

EXAMPLE.—The transverse diameter of an hyperbola (fig. 87) is 60 (D), the conjugate 36 (d), and the lesser abscissa or height, ge, 20 (a') ; what is the area of the figure ?

$60 \times 20 + \frac{4}{7}$ of $20^2 = 1485{\cdot}7143 =$ *sum of the product of the transverse and abscissa and* $\frac{4}{7}$ *of the square of the abscissa.*

$\sqrt{1485{\cdot}7143} \times 21 = 809{\cdot}424 = 21$ *times the square root of the above sum.*

$\sqrt{60 \times 20} \times 4 + 809{\cdot}424 = 947{\cdot}988 =$ *sum of above result and the root of* 4 *times the product of the transverse and abscissa.*

$947{\cdot}988 \div 75 = 12{\cdot}6398 =$ *quotient of above result ÷* 75.

$\frac{36 \times 20 \times 4}{60} \times 12{\cdot}6398 = 606{\cdot}7104 =$ *product of* 4 *times the product of the conjugate and abscissa ÷ the transverse and the above quotient = area.*

CYCLOIDAL CURVES.

The Cycloid.

A Cycloid is the curve formed by any point, p, on a circle, npq, whose radius $on = a$, rolling on a line, BC.

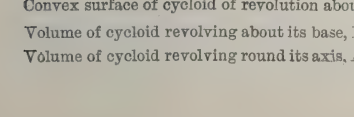

FIG. 88.

$Am = x$, $pm = y$, a = radius of generating circle.

Bn = arc $pn = a\theta$. $(\theta = pon.)$

Arc $Ap = 2\sqrt{2ax} = 2 \times$ chord of corresponding arc of generating circle.

Circumference BAC $= 8a$, BC $= 2\pi a$.

Area $= 3 \times$ area of generating circle $= 3\pi a^2$.

Convex surface of cycloid of revolution about base $= \frac{64}{3}\pi a^2$.

Convex surface of cycloid of revolution about axis $= 8\pi a^2\left(\pi - \frac{4}{3}\right)$.

Volume of cycloid revolving about its base, BC $= 5\pi^2 a^3$.

Volume of cycloid revolving round its axis, AD $= \frac{\pi}{6}(9\pi^2 - 16)a^3$.

The Trochoid.

The Trochoid is the curve traced by a point *within* the circumference of the circle which rolls on a straight line.

The Epicycloid and Hypocycloid.

The Epicycloid is formed by any point in a circle rolling on the convex arc of another circle; the Hypocycloid is formed by any point in a circle rolling on the concave arc of another circle.
a and b are the radii of the fixed and rolling circles.

Length of arc of epicycloid after one revolution of generating circle $= \frac{8b}{a}(a + b)$.

Length of arc of hypocycloid after one revolution of generating circle $= \frac{8b}{a}(a - b)$.

Area of epicycloid between curve and fixed circle after one revolution of rolling circle $\Big\} = \pi b^2\left(3 + \frac{2b}{a}\right)$.

Area of hypocycloid between curve and fixed circle after one revolution of rolling circle $\Big\} = \pi b^2\left(3 - \frac{2b}{a}\right)$.

EQUATIONS TO CURVES.

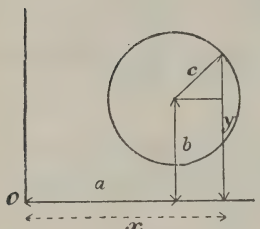

FIG. 89.

Circle.

General equation: $x^2 + y^2 - 2ax - 2by + a^2 + b^2 - c^2 = 0$.

If origin O is on the circumference, then $x^2 + y^2 - 2ax = 0$.

Equation to tangent: $y = mx + c\sqrt{1 + m^2}$,

where $m = -\frac{x'}{y'}$, x' and y' being the co-ordinates of the point on the circle at which the tangent is drawn.

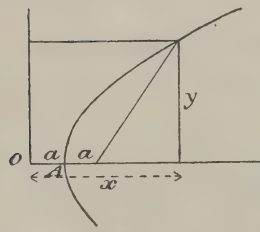

FIG. 90.

Parabola.

General equation: $y^2 = 4a(x - a)$.

If origin O is at A, then $y^2 = 4ax$.

Equation to tangent: $y = mx + \frac{a}{m}$,

where $m = \frac{2a}{y'}$, y' being the ordinate of the point on the curve at which the tangent is drawn.

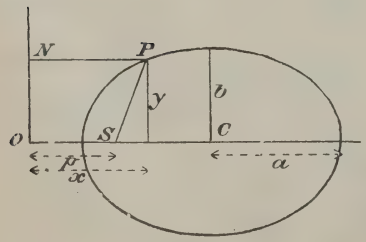

FIG. 91.

Ellipse.

$\frac{SP}{PN} = e =$ *less than* unity.

General equation: $y^2 + (x - p)^2 = e^2x^2$.

If the origin is at the centre, C, then—

$$y^2 = \frac{b^2}{a^2}(a^2 - x^2).$$

Equation to tangent: $y = mx + \sqrt{a^2m^2 + b^2}$, where $-\frac{b^2x'}{a^2y'} = m$, x' and y' being the co-ordinates of the point on the circle at which the tangent is drawn.

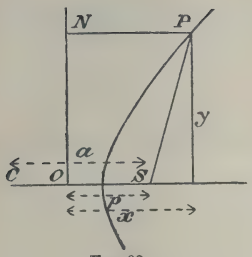

FIG. 92.

Hyperbola.

$$\frac{SP}{PN} = e = \textit{greater than} \text{ unity.}$$

General equation : $y^2 + (x - p)^2 = e^2x^2$.

If the origin is at the centre, C, then $y^2 = \frac{b^2}{a^2}(x^2 - a^2)$.

where $b^2 = (e^2 - 1)a^2$.

Equation to tangent : $y = mx + \sqrt{m^2a^2 - b^2}$.

The Logarithmic Curve.

In this curve the abscissa is the logarithm of the ordinate.

General equation : $y = a^x$,

where a is the base of the system.

Cycloidal Curves.

No rational algebraical equation expressing the relation of x to y can be found in the case of the Cycloid, Trochoid, Epicycloid, or Hypocycloid.

THE CATENARY.

(G. A. Burls.)

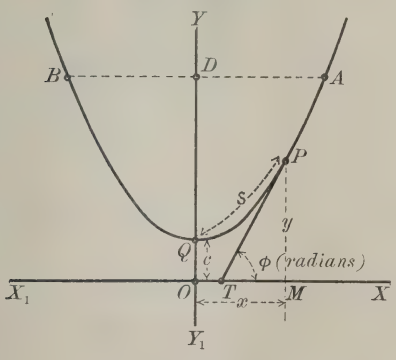

FIG. 93.

This is the curve in which a uniform, perfectly flexible, but inextensible, cord or chain hangs under the action of gravity. The weight of any portion of such a chain is proportional to its length, and accordingly it is usual to take as unit weight that of unit length of the chain.

Let A B (fig. 93) be the points of suspension; Q the lowest point; c the length of chain the weight of which is equal to the tension at Q. Take $QO = c$; then the equation to the curve referred to OX and OY as axes is:—

$$y = \frac{c}{2}\left\{ e^{\frac{x}{c}} + e^{-\frac{x}{c}} \right\} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

which is very simply expressed in the notation of hyperbolic functions thus:—

$$\frac{y}{c} = \cosh. \frac{x}{c} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

By aid of the table, pp. 103–104, the curve may readily be plotted.

The slope at any point P is given by:—

$$\tan \phi = \frac{dy}{dx} = \sinh. \frac{x}{c} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

and is also at once given by the table.

If the tension at P be equal to the weight of T units of length of the chain, then it is easily shown that:—

$$T = y = PM \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

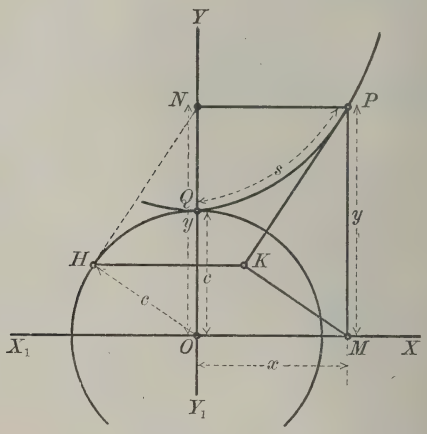

FIG. 94.

If the length of the chain from Q to P be denoted by s, then:—

$$s = c \sinh. \frac{x}{c} = c \tan \phi \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

Another simple and easily established expression for s is:—

$$s^2 = y^2 - c^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

With O as centre (fig. 94) and $OQ = c$ as radius, describe a circle.

Let P $(x\ y)$ be any point on the catenary ; draw the co-ordinates PM and PN.

From N draw NH, touching the circle at H ; and join OH.

Then ON $= y$. OH $= c$. Also as OHN is 90° :—

$$NH^2 = ON^2 - OH^2 = y^2 - c^2 = s^2 = QP^2, \text{ by (6).}$$

Thus NH is equal to the length of the arc QP of the catenary.

Also from (5) :—Tan $\phi = \frac{s}{c} = \frac{NH}{HO}$ = tan HON ; thus HON $= \phi$, and accordingly NH is parallel to the tangent to the catenary at P.

Through H draw HK parallel to OX meeting the tangent through P at K ; join KM. Then the triangles PKM and NHO are in all respects equal. And evidently K may be regarded as the free end of a string being unwound from the catenary, starting from Q, since PK = the arcual length PQ. Thus K is a point on the involute of the catenary starting from Q ; this involute is called the tractrix.

To find the catenary of given length, through any two points.

In fig. 95, given :—

$$P_1E = a = x_2 - x_1 ; \quad EP_2 = b = y_2 - y_1 ; \quad P_1P_2 = s$$

to find the axes, and the equation to P_1P_2.

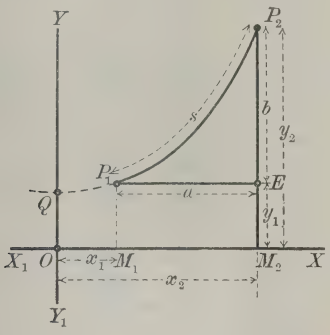

FIG. 95.

The value of c must first be found which satisfies the equation :—

$$\cosh.\frac{a}{c} = 1 + \frac{\frac{1}{2}(s^2 - b^2)}{c^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

This is easily done by trial by aid of the table on pp. 103–104.

Knowing c we next find $(x_2 + x_1)$ from the equation :—

$$\coth.\frac{x_2 + x_1}{2c} = \frac{s}{b} \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

and as $x_2 - x_1 = a$, x_2 and x_1 are known.

Then as $y_1 = c \cosh.\frac{x_1}{c}$, $y_2 = c \cosh.\frac{x_2}{c}$, y_1 and y_2 are also known. Thus the axes are located and the equation is found.

s and l (= AB, fig. 93) are commonly known. Let $\frac{s}{l} = k$; then k is known.

c may now be found by aid of the equation:—

$$\frac{\sinh.\left(\frac{l}{2c}\right)}{\left(\frac{l}{2c}\right)} = k \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (9)$$

To facilitate the use of this equation the table on page 39 has been prepared, giving a sufficient range of values of $\frac{\sinh.\theta}{\theta}$ for ordinary practice. From this table, in any specific case θ is at once recognised; then $\frac{l}{2c} = \theta$, so that

$$c = \frac{l}{2\theta} \quad . \quad . \quad . \quad . \quad (10)$$

and is at once determined.

Knowing c, all the quantities connected with the curve are immediately determinable by aid of the equations above given.

Spirals.

The Spiral of Archimedes.—In this spiral the radius vector varies directly as the angle described.

General equation: $r = a\theta$,

where $a = \frac{c}{2\pi}$ if c be the value of r when $\theta = 2\pi$.

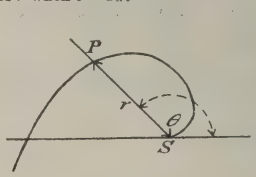

FIG. 96.

Let a line revolve uniformly round S, while a point, P, moves uniformly from S along it; then P will trace the Spiral of Archimedes.

The Logarithmic Spiral.—Here the angle described is the logarithm of the radius vector.

General equation: $r = a^{\theta}$.

It is also called the equiangular spiral, since it cuts the radius at a constant angle.

The Hyperbolic Spiral.—In this spiral as the angle increases at a uniform rate the radius vector decreases at an hyperbolic rate.

General equation: $r = \frac{a}{\theta}$.

TABLE OF VALUES OF $\frac{\text{Sinh. } \theta}{\theta}$.

Involute of a Circle.

This curve is described by the extremity of a string which is uncoiled from the circumference of a circle.

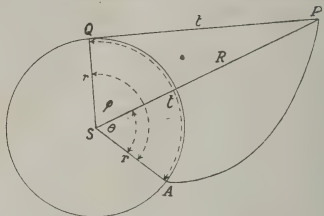

FIG. 97.

A, the point from which the string began to be unwrapped; QP (at right angles to QS), the string once coincident with, and therefore equal to, the arc AQ; ϕ, the angle QSA; θ, the angle PSA; join SP, then $t = \phi r \frac{2\pi}{360}$, in angular measure $= \phi r$, in circular measure; also

$$\theta = \frac{\sqrt{R^2 - r^2}}{r} - \tan^{-1}\frac{\sqrt{R^2 - r^2}}{r}, \text{ in circular measure.}$$

$\left(\tan^{-1}\frac{\sqrt{R^2-r^2}}{r}\right.$ is the angle (in circular measure) whose tangent is $\left.\frac{\sqrt{R^2-r^2}}{r}\right)$.

THE CIRCLE.

Formulæ.

d = diameter. r = radius. p = periphery or circumference. A = area.

π = ratio of circumference to diameter.

Periphery or Circumference.

$p = \pi d = 3{\cdot}14159d.$

$= 2\pi r = 6{\cdot}2832r.$

$= 2\sqrt{\pi A} = 3{\cdot}54\sqrt{A}.$

$= \frac{2A}{r} = \frac{4A}{d}.$

Diameter and Radius.

$d = \frac{p}{\pi} = \frac{p}{3{\cdot}14159}.$

$= 2\sqrt{\frac{A}{\pi}} = 1{\cdot}12838\sqrt{A}.$

$r = \frac{p}{2\pi} = \frac{p}{6{\cdot}2832}$

$= \sqrt{\frac{A}{\pi}} = 0{\cdot}56419\sqrt{A}.$

Area.

$A = \frac{\pi d^2}{4} = 0{\cdot}7854d^2.$

$= \pi r^2 = 3{\cdot}14159r^2.$

$= \frac{p^2}{4\pi} = \frac{p^2}{12{\cdot}566}.$

$= \frac{pr}{2} = \frac{pd}{4}.$

$\pi = 3{\cdot}1415926536.$

An approximate value of π is $\frac{22}{7}$, but a *much nearer* value is $\frac{355}{113}$, which is true as far as six places of decimals. The last fraction is easily remembered by writing down the first three odd numbers twice and dividing them in the middle, thus, 113 | 355.

$2\pi = 6{\cdot}283185.$	$6\pi = 18{\cdot}849556.$	$\frac{\pi}{2} = 1{\cdot}570796.$	$\frac{\pi}{8} = 0\ 392699.$	$\frac{1}{\pi} = 0{\cdot}318310.$	$\frac{6}{\pi} = 1{\cdot}909859.$	
$3\pi = 9{\cdot}424778.$	$7\pi = 21{\cdot}991148.$	$\frac{\pi}{3} = 1\ 047197.$	$\frac{\pi}{12} = 0{\cdot}261799.$	$\frac{2}{\pi} = 0{\cdot}636619.$	$\frac{8}{\pi} = 2{\cdot}546478.$	
$4\pi = 12{\cdot}566370.$	$8\pi = 25{\cdot}132741.$	$\frac{\pi}{4} = 0{\cdot}785398.$	$\frac{2\pi}{3} = 2{\cdot}094394.$	$\frac{3}{\pi} = 0{\cdot}954929.$	$\frac{12}{\pi} = 3{\cdot}819718.$	
$5\pi = 15{\cdot}707963.$	$9\pi = 28{\cdot}274334.$	$\frac{\pi}{6} = 0{\cdot}523599.$	$\frac{\pi}{360} = 0{\cdot}008726.$	$\frac{4}{\pi} = 1{\cdot}273239.$	$\frac{360}{\pi} = 114{\cdot}5915.$	
$\pi^2 = 9{\cdot}869650.$	$\sqrt{\pi} = 1{\cdot}772453.$	$\sqrt{\frac{1}{\pi}} = 0{\cdot}564189.$	$\sqrt{\frac{\pi}{2}} = 1{\cdot}253314.$	$\sqrt{\frac{2}{\pi}} = 0{\cdot}797884$	$\text{Log } \pi = 0{\cdot}49714987.$	

CIRCUMFERENCE AND AREA OF CIRCLES.

* For Diameters advancing by 'Tenths,' shift the decimal point one place to the left for Circumferences, and two p'aces to the left for Areas.

EXAMPLE.—What is the circumference and the area of a circle whose diameter is 1·7 (i.e. 17 tenths)?
Circumference = 5·3407; Area = 2·2698.

TABLE OF SEGMENTS, CHORDS, ZONES, &c., OF A CIRCLE.

To find the Angle of an Arc of a Circle.

RULE.—Divide the chord of the arc by its height, and find the quotient in the first column. The corresponding number in the *second* column is the angle of the arc in degrees of the circle.

To find the Radius of an Arc of a Circle.

RULE.—Divide the chord of the arc by its height, and find the quotient in the first column. The corresponding number in the *third* column, multiplied by the chord, is the radius of the arc.

To find the Length of an Arc of a Circle.

RULE.—Divide the chord of the arc by its height, and find the quotient in the first column. The corresponding number in the *fourth* column, multiplied by the chord, is the length of the arc.

To find the Area of a Segment of a Circle.

RULE.—Divide the chord of the segment by its height, and find the quotient in the first column. The corresponding number in the *fifth* column, multiplied by the square of the chord, is the area of the segment.

To find the Surface of a Circle Zone.

RULE.—Divide the chord of the zone by its height, and find the quotient in the first column. The corresponding number in the *sixth* column, multiplied by the *square* of the chord, is the surface of the zone.

To find the Solidity of a Circle Zone.

RULE.—Divide the chord of the zone by its height, and find the quotient in the first column. The corresponding number in the *seventh* column, multiplied by the *cube* of the chord, is the solidity of the zone.

To find the Chord of an Arc of a Circle.

RULE.—In column *eight* find the chord corresponding to the angle of the arc given in column two, and multiply the value by the radius of the circle.

FORMULÆ.

The following are the formulæ from which the values in the following tables (pp. 50-55) were calculated :—

Col. 1. $2 \cot \frac{v}{4}$.

Col. 3. $\frac{\operatorname{cosec} \frac{v}{2}}{2}$.

Col. 4. $\frac{\operatorname{cosec} \frac{v}{2}}{2} \times \frac{\pi v}{180}$.

Col. 5. $\frac{\operatorname{cosec}^2 \frac{v}{2}}{8}\left(\frac{\pi v}{180} - \sin v\right)$.

Col. 6. $\frac{\pi}{4 - 2 \operatorname{versin} \frac{v}{2}}$.

Col. 7. $\frac{\pi}{24}\left(\operatorname{cosec} \frac{v}{2} - \cot \frac{v}{2}\right)^2 \left(2 \operatorname{cosec} \frac{v}{2} + \cot \frac{v}{2}\right)$.

Col. 8. Ordinary Table of Chords.

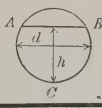
Area of segment ABC = tabular value a corresponding to $\frac{h}{d}$, multiplied by d^2.



Example:—If $d = 48$ ins., $h = 5$ ins.; then $\frac{h}{d} = \frac{5}{48} = \cdot104$; tabular value a corresponding to $\cdot104 = \cdot04330$; then area of segment ABC $= \cdot04330 \times 48 \times 48 = 99{\cdot}76$ sq. ins.

TRIGONOMETRY.

Trigonometry is the science in which the relations subsisting between the sides and angles of a triangle are investigated. The science is called *plane* trigonometry or *spherical* trigonometry according as the triangle is formed on a plane surface or on a spherical surface. Plane trigonometry also includes all algebraical investigations with respect to plane angles, whether forming a triangle or not.

Measurement of Angles.

In practice the *right angle*, or some fraction of it, is always taken as the unit of angular measurement. It is divided into 90 equal parts, called degrees (°), each degree into 60 minutes (′), and each minute into 60 seconds (″). The *centesimal* method, in which the right angle is divided into 100 equal parts (grades), &c., is not used even in France, where it was first proposed. In theoretical investigations, what is termed the *circular measure* of angles is frequently employed. In this system the unit of measurement is the *radian*—that is, the angle which at the centre of the circle stands on an arc equal in length to the radius of the circle. The radian $= \frac{2 \text{ right angles}}{\pi}$ $= 57{\cdot}295779 \ldots$ degrees. Since π radians $= 2$ right angles, π ($= 3{\cdot}14159 \ldots$ radians) is often used to denote an angle of 180°. Similarly, $\frac{\pi}{2} = 90°$, $\frac{\pi}{4} = 45°$, &c. Rectangular measure may be expressed in circular measure, and *vice versâ*, by means of the following formulæ :—

$$D = \frac{180\theta}{\pi}, \qquad \theta = \frac{\pi D}{180},$$

in which D = the number of *degrees*, and θ = the number of *radians* in the given angle.

A triangle contains seven quantities—namely, three sides, three angles, and the surface. When any three of these quantities are given, the four remaining ones can by them be ascertained (one side or the area must be one of the given quantities). This operation is called *solving the triangle*, and is simply an application of arithmetic to geometrical objects.

For the foundation of the above-mentioned solution there are assumed eight *trigonometrical functions*, as follows :—

Let ABC (fig. 98) be a right-angled triangle, C being the right angle ; then

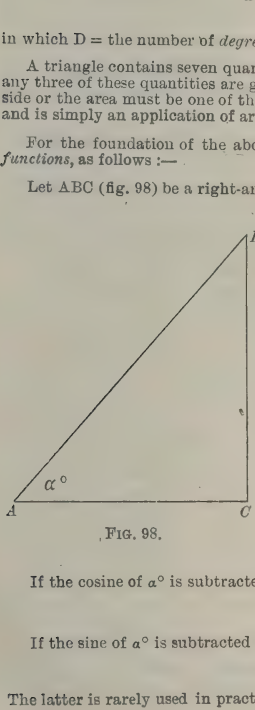

FIG. 98.

$$\frac{BC}{AB}, \text{ or } \frac{\text{perpendicular}}{\text{hypotenuse}} = \text{sine } \alpha°.$$

$$\frac{AC}{AB}, \text{ or } \frac{\text{base}}{\text{hypotenuse}} = \text{cosine } \alpha°.$$

$$\frac{BC}{AC}, \text{ or } \frac{\text{perpendicular}}{\text{base}} = \text{tangent } \alpha°.$$

$$\frac{AC}{BC}, \text{ or } \frac{\text{base}}{\text{perpendicular}} = \text{cotangent } \alpha°.$$

$$\frac{AB}{AC}, \text{ or } \frac{\text{hypotenuse}}{\text{base}} = \text{secant } \alpha°.$$

$$\frac{AB}{BC}, \text{ or } \frac{\text{hypotenuse}}{\text{perpendicular}} = \text{cosecant } \alpha°.$$

If the cosine of $\alpha°$ is subtracted from unity, the remainder is called the *versed sine* of $\alpha°$; i.e.

$$1 - \cos \alpha° = \text{versin } \alpha°.$$

If the sine of $\alpha°$ is subtracted from unity, the remainder is called the *coversed sine* of $\alpha°$; i.e.,

$$1 - \sin \alpha° = \text{coversin } \alpha°.$$

The latter is rarely used in practice.

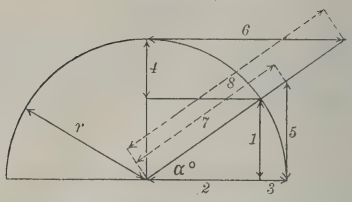

FIG. 99.

If in the figure (fig. 99) the radius r is unity, the values of the different lengths 1, 2, 3, 4, 5, 6, 7, 8, represent the values of the trigonometrical functions of the angle $\alpha°$ as follows :—

1	represents	the	value of	sine $\alpha°$.	5	represents	the value of	tan $\alpha°$.
2	,,	,,	,,	cosine $\alpha°$.	6	,,	,,	,, cot $\alpha°$.
3	,,	,,	,,	versin $\alpha°$.	7	,,	,,	,, sec $\alpha°$.
4	,,	,,	,,	coversin $\alpha°$.	8	,,	,,	,, cosec $\alpha°$.

The *complement* of an angle $\alpha° = 90° - \alpha°$. The *supplement* of an angle $\alpha° = 180° - \alpha°$

Relations of Trigonometrical Functions to each other.

$$\operatorname{cosec} \alpha = \frac{1}{\sin \alpha}. \qquad \sec \alpha = \frac{1}{\cos \alpha}. \qquad \cot \alpha = \frac{1}{\tan \alpha}.$$

$$\tan \alpha = \frac{\sin \alpha}{\cos \alpha}. \qquad \cot \alpha = \frac{\cos \alpha}{\sin \alpha}. \qquad \sin^2 \alpha + \cos^2 \alpha = 1.$$

$$\tan^2 \alpha + 1 = \sec^2 \alpha. \qquad \cot^2 \alpha + 1 = \operatorname{cosec}^2 \alpha.$$

$$\sin \alpha = \sqrt{1 - \cos^2 \alpha} = \frac{1}{\sqrt{1 + \cot^2 \alpha}} = \frac{\tan \alpha}{\sqrt{1 + \tan^2 \alpha}}. \qquad \cos \alpha = \sqrt{1 - \sin^2 \alpha} = \frac{1}{\sqrt{1 + \tan^2 \alpha}}.$$

$$\tan \alpha = \frac{\sin \alpha}{\sqrt{1 - \sin^2 \alpha}}. \qquad \cot \alpha = \frac{\sqrt{1 - \sin^2 \alpha}}{\sin \alpha} \qquad \operatorname{cosec} \alpha = \sqrt{1 + \cot^2 \alpha} = \frac{\sqrt{1 + \tan^2 \alpha}}{\tan \alpha}.$$

$$\sec \alpha = \sqrt{1 + \tan^2 \alpha}. \qquad \operatorname{versin} \alpha = 1 - \frac{1}{\sqrt{1 + \tan^2 \alpha}}.$$

$$\sin \alpha = \sin (180 - \alpha) = - \sin (180 + \alpha).$$
$$\cos \alpha = - \cos (180 - \alpha) = - \cos (180 + \alpha).$$
$$\tan \alpha = - \tan (180 - \alpha) = \tan (180 + \alpha).$$
$$\cot \alpha = - \cot (180 - \alpha) = \cot (180 + \alpha).$$
$$\sec \alpha = - \sec (180 - \alpha) = - \sec (180 + \alpha).$$
$$\operatorname{cosec} \alpha = \operatorname{cosec} (180 - \alpha) = - \operatorname{cosec} (180 + \alpha).$$
$$\operatorname{versin} (180 - \alpha) = 1 + \cos \alpha.$$
$$\sin \alpha = - \cos (90 + \alpha). \qquad \cos \alpha = \sin (90 + \alpha).$$

$$\sin (\alpha + \beta) = \sin \alpha \cos \beta + \cos \alpha \sin \beta.$$
$$\sin (\alpha - \beta) = \sin \alpha \cos \beta - \cos \alpha \sin \beta.$$
$$\cos (\alpha + \beta) = \cos \alpha \cos \beta - \sin \alpha \sin \beta.$$
$$\cos (\alpha - \beta) = \cos \alpha \cos \beta + \sin \alpha \sin \beta.$$
$$\tan (\alpha + \beta) = \frac{\tan \alpha + \tan \beta}{1 - \tan \alpha \tan \beta}.$$
$$\tan (\alpha - \beta) = \frac{\tan \alpha - \tan \beta}{1 + \tan \alpha \tan \beta}.$$
$$\sin (\alpha + \beta) \sin (\alpha - \beta) = \sin^2 \alpha - \sin^2 \beta = \cos^2 \beta - \cos^2 \alpha.$$
$$\cos (\alpha + \beta) \cos (\alpha - \beta) = \cos^2 \alpha - \sin^2 \beta = \cos^2 \beta - \sin^2 \alpha.$$

$$\sin 2\alpha = 2\sin\alpha\cos\alpha = \frac{2\tan\alpha}{1+\tan^2\alpha}.$$

$$\cos 2\alpha = \cos^2\alpha - \sin^2\alpha = 1 - 2\sin^2\alpha = 2\cos^2\alpha - 1 = \frac{1-\tan^2\alpha}{1+\tan^2\alpha}.$$

$$\tan 2\alpha = \frac{2\tan\alpha}{1-\tan^2\alpha}. \qquad \cot 2\alpha = \frac{\cot^2\alpha - 1}{2\cot\alpha}.$$

$$\sin 3\alpha = 3\sin\alpha - 4\sin^3\alpha. \qquad \cos 3\alpha = 4\cos^3\alpha - 3\cos\alpha.$$

$$\tan 3\alpha = \frac{3\tan\alpha - \tan^3\alpha}{1 - 3\tan^2\alpha}.$$

$$\sin\frac{\alpha}{2} = \sqrt{\frac{1-\cos\alpha}{2}}. \qquad \cos\frac{\alpha}{2} = \sqrt{\frac{1+\cos\alpha}{2}}.$$

$$\tan\frac{\alpha}{2} = \sqrt{\frac{1-\cos\alpha}{1+\cos\alpha}} = \frac{1-\cos\alpha}{\sin\alpha} = \frac{-1 \pm \sqrt{1+\tan^2\alpha}}{\tan\alpha}.$$

Formulæ for Right-angled Triangles.

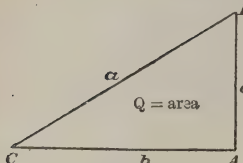

FIG. 100.

$$a = \sqrt{b^2+c^2} = \frac{c}{\sin C} = \frac{b}{\cos C} = 2\sqrt{\frac{Q}{\sin 2C}}.$$

$$b = a\cos C = c\cot C = a\sin B = c\tan B = \sqrt{\frac{2Q}{\tan C}}$$

$$Q = \frac{a^2\sin 2C}{4} = \frac{b^2\tan C}{2} = \frac{c^2\sin 2C}{2} = \frac{c\sqrt{(a+c)(a-c)}}{2}.$$

$$\sin C = \frac{c}{a};\ \cos C = \frac{b}{a};\ \tan C = \frac{c}{b} = \frac{2Q}{b^2};\ \sin 2C = \frac{4Q}{a^2}.$$

Formulæ for Oblique-angled Triangles.

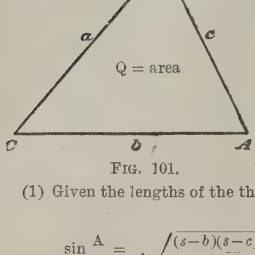

FIG. 101.

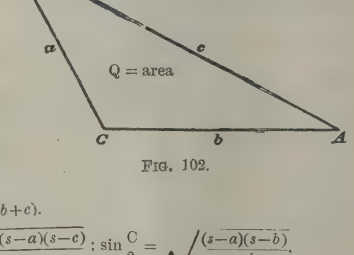

FIG. 102.

(1) Given the lengths of the three sides, a, b, c.

$$s = \tfrac{1}{2}(a+b+c).$$

$$\sin\frac{A}{2} = \sqrt{\frac{(s-b)(s-c)}{bc}};\ \sin\frac{B}{2} = \sqrt{\frac{(s-a)(s-c)}{ac}};\ \sin\frac{C}{2} = \sqrt{\frac{(s-a)(s-b)}{ab}}.$$

$$\cos\frac{A}{2} = \sqrt{\frac{s(s-a)}{bc}};\quad \cos\frac{B}{2} = \sqrt{\frac{s(s-b)}{ac}};\quad \cos\frac{C}{2} = \sqrt{\frac{s(s-c)}{ab}}.$$

$$\tan\frac{A}{2} = \sqrt{\frac{(s-b)(s-c)}{s(s-a)}};\ \tan\frac{B}{2} = \sqrt{\frac{(s-a)(s-c)}{s(s-b)}};\ \tan\frac{C}{2} = \sqrt{\frac{(s-a)(s-b)}{s(s-c)}}.$$

(2) Given one side and two adjacent angles, viz. a, B, C.

$$A = 180 - (B+C);\qquad b = a\frac{\sin B}{\sin A};\qquad c = a\frac{\sin C}{\sin A}.$$

(3) Given two sides and the included angle, viz. b, c, A.

$\tan\frac{B-C}{2} = \frac{b-c}{b+c}\cot\frac{A}{2}$, from which $\frac{B-C}{2}$ can be determined; then $B = \frac{B-C}{2} + 90 - \frac{A}{2}$.

(4) Given two sides and the angle opposite one of them, viz. a, b, A.

$$\sin B = \frac{b}{a}\sin A;\qquad C = 180 - (A+B);\qquad b = a\frac{\sin C}{\sin A},$$

in which if

A is not less than 90°	C must be acute :
a is less than b sin A	there is no solution ;
a equals b sin A	C is a right angle ;
a is greater than b sin A	C may be acute or obtuse ;
a equals or is greater than b	C must be acute.

$$Q = \frac{bc\sin A}{2} = \frac{ac\sin B}{2} = \frac{ab\sin C}{2} = \frac{c^2\sin A\sin B}{2\sin(A+B)} = \sqrt{s(s-a)(s-b)(s-c)}.$$

$$a = \sqrt{\frac{2Q\sin A}{\sin B\sin(A+B)}};\qquad b = \sqrt{\frac{2Q\sin B}{\sin C\sin(B+C)}};\qquad c = \sqrt{\frac{2Q\sin C}{\sin A\sin(A+C)}}$$

$$a = \sqrt{b^2+c^2-2bc\cos A}.$$

SPHERICAL TRIGONOMETRY.

Spherical Trigonometry treats of triangles which are drawn (or imagined to be) on the surface of a sphere. Their sides are arcs of the great circle of the sphere, and are measured by the angle of the arc. Therefore the trigonometrical functions bear quite a different relation to the sides.

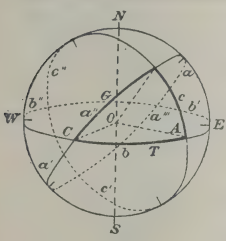

FIG. 103.

Every section of a sphere cut by a plane is a *circle*. A line drawn through the centre and at right angles to the sectional circle is called an *axis*, and the two points where the axis meets the surface of the sphere are called the *poles* of the sectional circle.

When the cutting-plane goes through the centre of the sphere, it will pass through the great circle, and is then called the *Equator* for the poles. Axis = NS. Equator = GETW.

Three great circle-planes, $a\,a'\,a''\,a'''$, $b\,b'\,b''$, and $c\,c'\,c''$, cutting a sphere, NESW, will form a solid angle at the centre O, and a triangle ABC on the surface of the sphere, in which the arcs a, b, c, are the sides. The angles formed by each two planes are congruent to each of the appertinent angles A, B, and C.

Spherical Distances.

For the spherical distances, let

l = lower latitude, in degrees from the equator.
l' = highest latitude " " "
C = course, from the latitude l to l'.
C′ = course, from the latitude l' to l.
d = shortest distance between l and l', in degrees of the great circle.
L = difference in longitude between l and l', in degrees, or time.
$\tan m = \cot l' \cos \mathrm{L}$.
$n = 90 \mp l - m$
$-\ l$, when l and l' are on one side of the equator.
$+\ l$, when l is on one side, and l' on the other. Then

$$\cos d = \frac{\sin l' \cos n}{\cos m}. \qquad \sin \mathrm{C} = \frac{\sin \mathrm{L} \cos l'}{\sin d}. \qquad \sin \mathrm{C}' = \frac{\sin \mathrm{L} \cos l}{\sin d}.$$

Formulæ for Right-angled Spherical Triangles.

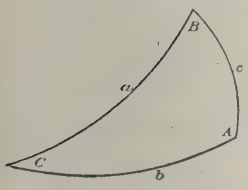

FIG. 104.

$$\sin b = \sin a \sin \mathrm{B}. \qquad \tan c = \tan a \cos \mathrm{B}.$$
$$\cot \mathrm{C} = \cos a \tan \mathrm{B}. \qquad \tan c = \sin b \tan \mathrm{C}.$$
$$\cos a = \cos b \cos c. \qquad \cos \mathrm{B} = \cos b \sin \mathrm{C}.$$
$$\tan a = \frac{\tan b}{\cos \mathrm{C}}. \qquad \sin c = \frac{\tan b}{\tan \mathrm{B}}.$$
$$\sin a = \frac{\sin b}{\sin \mathrm{B}}. \qquad \sin \mathrm{C} = \frac{\cos \mathrm{B}}{\cos b}.$$
$$\cos c = \frac{\cos a}{\cos b}. \qquad \sin \mathrm{B} = \frac{\sin b}{\sin a}.$$
$$\cos \mathrm{C} = \frac{\tan b}{\tan a}. \qquad \tan \mathrm{C} = \frac{\tan c}{\sin b}.$$

$$\tan \mathrm{B} = \frac{\tan b}{\sin c}. \qquad \cos c = \frac{\cos \mathrm{C}}{\sin \mathrm{B}}. \qquad \cos b = \frac{\cos \mathrm{B}}{\sin \mathrm{C}}. \qquad \cos a = \frac{\cot \mathrm{C}}{\tan \mathrm{B}}.$$

Formulæ for Oblique-angled Spherical Triangles.

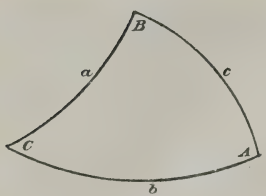

FIG. 105.

$$\sin a : \sin b = \sin A : \sin B. \qquad \sin b : \sin c = \sin B : \sin C.$$

$$\sin a = \frac{\sin b \sin A}{\sin B}. \qquad \sin b = \frac{\sin c \sin B}{\sin C}.$$

$$\tan \tfrac{1}{2}(a+b) = \tan \tfrac{1}{2}c \, \frac{\cos \tfrac{1}{2}(A-B)}{\cos \tfrac{1}{2}(A+B)}.$$

$$\tan \tfrac{1}{2}(a-b) = \tan \tfrac{1}{2}c \, \frac{\sin \tfrac{1}{2}(A-B)}{\sin \tfrac{1}{2}(A+B)}.$$

$$\tan \tfrac{1}{2}(B+C) = \cot \tfrac{1}{2}A \, \frac{\cos \tfrac{1}{2}(b-c)}{\cos \tfrac{1}{2}(b+c)}.$$

$$\tan \tfrac{1}{2}(B-C) = \cot \tfrac{1}{2}A \, \frac{\sin \tfrac{1}{2}(b-c)}{\sin \tfrac{1}{2}(b+c)}.$$

$$\cot \tfrac{1}{2}A = \tan \tfrac{1}{2}(B-C) \frac{\sin \tfrac{1}{2}(b+c)}{\sin \tfrac{1}{2}(b-c)}. \qquad \tan \tfrac{1}{2}c = \tan \tfrac{1}{2}(a-b) \frac{\sin \tfrac{1}{2}(A+B)}{\sin \tfrac{1}{2}(A-B)}.$$

$$\tan \tfrac{1}{2}(m+n) \tan \tfrac{1}{2}(m-n) = \tan \tfrac{1}{2}(a+c) \tan \tfrac{1}{2}(a-c).$$

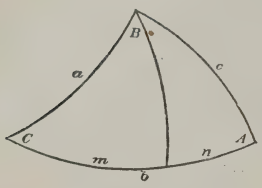

FIG. 106.

$$\tan m = \tan a \cos C. \qquad \tan C = \frac{\sin (b-m) \tan A}{\sin m}.$$

$$\cos C = \frac{\cos a \cos (b-m)}{\cos m}. \qquad \cos n = \frac{\cos c \cos m}{\cos c}.$$

$$b = m \pm n.$$

$$s = \tfrac{1}{2}(a+b+c). \qquad S = \tfrac{1}{2}(A+B+C).$$

$$\sin \tfrac{1}{2}A = \sqrt{\frac{\sin (s-c) \sin (s-b)}{\sin b \sin c}}. \qquad \sin \tfrac{1}{2}a = \sqrt{\frac{\cos S \cos (S-A)}{\sin B \sin C}}.$$

To find the Area of a Spherical Triangle.

Let Q be the area of the triangle in square degrees ; if R = radius of the sphere, the length of one degree will be

$$= \frac{2\pi R}{360}, \text{ or one square degree} = \frac{R^2}{3285{\cdot}58}.$$

$$\cot \tfrac{1}{2}Q = \frac{\cot \tfrac{1}{2}c \cot \tfrac{1}{2}a + \cos B}{\sin B}. \qquad \sin \tfrac{1}{2}Q = \frac{\sin \tfrac{1}{2}c \sin \tfrac{1}{2}a \sin B}{\cos \tfrac{1}{2}b}.$$

The sum of the three angles in a spherical triangle is greater than two right angles, and less than six right angles

SQUARES—CUBES—ROOTS—RECIPROCALS.

TABLE OF SQUARES, CUBES, SQUARE AND CUBE ROOTS, AND RECIPROCALS, OF NUMBERS FROM 1 TO 1,000.

Number.	Squares.	Cubes.	$\sqrt{\text{Roots.}}$	$\sqrt[3]{\text{Roots.}}$	Reciprocals.	Number.	Squares.	Cubes.	$\sqrt{\text{Roots.}}$	$\sqrt[3]{\text{Roots.}}$	Reciprocals.

Characteristic of log. of number containing one or more integral figs. is one *less* than the number of integral figs., and is positive.

Characteristic of log. of a number wholly decimal is one *more* than number of noughts at commencement of decimal, and is negative.

To multiply by logs., add logs., and find corresponding numbers.

To divide by logs., subtract logs., and find corresponding numbers.

To extract the root, divide log. by index, and find corresponding numbers.

To obtain any power, multiply log. by index, and find corresponding numbers.

Use of Differences.

Ex. 1.—Find the log. of 32685.

Difference (D) for 326 = 133 | log. 32680 = 4·514282†

133 × 5 = 665*

4·5143485

In all cases last fig. of * must be set one beyond last fig. of †.

Ex. 2.—Find number corresponding to log. 3·774743

Given log. . . . 3·774743

Nearest log. in table . . 3·774736 = log. 5953

Divide by Difference (D) 73)7 ·01

Required number = 5953·1

Hyperbolic or Natural Logarithms.

Hyp. log. = Common log. × 2·30258509. Common log. = Hyp. log. × ·43429448

HYPERBOLIC FUNCTIONS.

(G. A. Burls.)

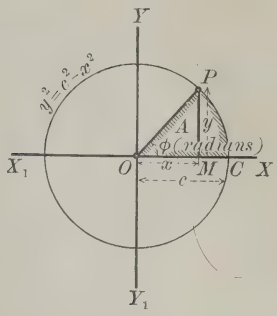

FIG. 107.

In the circle (fig. 107) $y^2=c^2-x^2$ if A denotes the area of the sector OCP and if ϕ be the angle COP, *in radians*, then :—

$$\phi = \frac{2}{c^2}.A \qquad (1)$$

and, by definition, we have also :—

$$\left.\begin{aligned} \frac{y}{c} &= \frac{PM}{OC} = \sin\phi \\ \frac{x}{c} &= \frac{OM}{OC} = \cos\phi \\ \frac{y}{x} &= \frac{PM}{OM} = \tan\phi \end{aligned}\right\} \qquad (2)$$

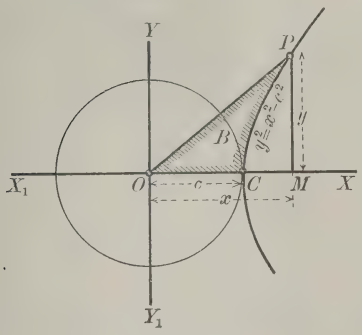

FIG. 108.

Similarly, in the rectangular hyperbola (fig. 108) $y^2=x^2-c^2$ it is found convenient to define corresponding ratios thus :—

$$\left.\begin{aligned} \frac{y}{c} &= \frac{PM}{OC} = \text{sinh.}\,\theta \\ \frac{x}{c} &= \frac{OM}{OC} = \text{cosh.}\,\theta \\ \frac{y}{x} &= \frac{PM}{OM} = \text{tanh.}\,\theta \end{aligned}\right\} \qquad (3)$$

Where θ is a quantity such that if B be the area of the hyperbolic sector OCP :—

$$\theta = \frac{2}{c^2}.B \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

In ordinary notation, $\phi = \sin^{-1}\frac{y}{c}$; similarly it may be shown that $\theta = \text{Log}_e\left(\frac{x+y}{c}\right)$.

Just as in the ordinary trigonometrical or 'circular' functions we have the fundamental identities :—

$$\left.\begin{aligned} \cos^2\phi + \sin^2\phi &= 1 \\ \sec^2\phi &= 1 + \tan^2\phi \\ \text{cosec}^2\phi &= 1 + \cot^2\phi \end{aligned}\right\} \text{etc.,}$$

so also in the hyperbolic functions we have :—

$$\left.\begin{aligned} \cosh^2\theta - \sinh^2\theta &= 1 \\ \text{sech}^2\theta &= 1 - \tanh^2\theta \\ \text{cosech}^2\theta &= \coth^2\theta - 1 \end{aligned}\right\} \text{etc.}$$

Moreover, the exponential values of the functions show corresponding similarities ; thus we have, ι denoting $\sqrt{-1}$:—

$$\sin\phi = \frac{1}{2\iota}\left\{e^{\iota\phi} - e^{-\iota\phi}\right\} = \phi - \frac{\phi^3}{\lfloor 3} + \frac{\phi^5}{\lfloor 5} - \frac{\phi^7}{\lfloor 7} + \cdots$$

while :

$$\sinh\theta = \frac{1}{2}\left\{e^{\theta} - e^{-\theta}\right\} = \theta + \frac{\theta^3}{\lfloor 3} + \frac{\theta^5}{\lfloor 5} + \frac{\theta^7}{\lfloor 7} + \cdots$$

And again :

$$\cos\phi = \frac{1}{2}\left\{e^{\iota\phi} + e^{-\iota\phi}\right\} = 1 - \frac{\phi^2}{\lfloor 2} + \frac{\phi^4}{\lfloor 4} - \frac{\phi^6}{\lfloor 6} + \cdots$$

while :

$$\cosh\theta = \frac{1}{2}\left\{e^{\theta} + e^{-\theta}\right\} = 1 + \frac{\theta^2}{\lfloor 2} + \frac{\theta^4}{\lfloor 4} + \frac{\theta^6}{6} + \cdots$$

Relation between the *quantity* θ and the *radian-angle* ϕ :—

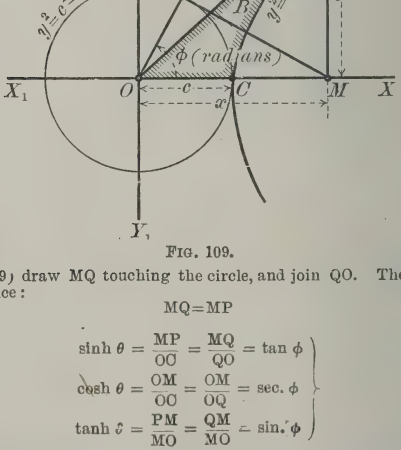

FIG. 109.

From M (fig. 109) draw MQ touching the circle, and join QO. Then $MQ^2 = OM^2 - OQ^2 = x^2 - c^2 = y^2 = PM^2$; hence :

$$MQ = MP$$

Consequently :

$$\left.\begin{aligned} \sinh\theta &= \frac{MP}{OC} = \frac{MQ}{QO} = \tan\phi \\ \cosh\theta &= \frac{OM}{OC} = \frac{OM}{OQ} = \sec.\phi \\ \tanh\theta &= \frac{PM}{MO} = \frac{QM}{MO} = \sin.\phi \end{aligned}\right\}$$

Discussion of many problems is much facilitated by use of hyperbolic functions ; see, for example, 'The Catenary,' p. 35.

THE SLIDE-RULE.

On the face of the ordinary (e.g. 10 in.) slide-rule, four scales, usually referred to as the A, B, C and D scales, are marked. A and D are on the rule, top and bottom, whilst B and C are marked upon the slide, and when the latter has not been moved either to the right or left, the divisions on A and B and also on C and D coincide. The graduation of the divisions of each of the scales is logarithmic, that is to say, the distance from the initial point of a scale to any number thereon represents the logarithm of that number.

The A and B scales are divided into primary graduations representing the logs of the numbers from unity to 100, and these divisions are each subdivided into ten secondary divisions. These, towards the left-hand side of the scales, are further subdivided, but as, in the progression towards the right-hand side, the primary divisions approach one another rapidly, it is not possible to carry the extreme sub-division throughout the scale. Inspection of any rule will show the extent to which such subdivision is practicable.

The C and D scales are divided similarly to the A and B scales, but here there are only ten primary divisions spread over the same length of scale as the 100 in the A and B scales. This admits of a greatly extended subdivision, affording a somewhat greater facility for accuracy in calculation. It may be observed here that the ratio between the two sets of scales involves the fact that the figures on the A and B scales are the squares of those on the C and D scales; conversely the figures on the C and D scales are of course the square roots of those on the A and B scales.

Most rules are also provided with a sliding runner, referred to as the 'Cursor,' which is enabled to slide along the length of the rule parallel to the scales. The cursor usually consists of a small frame carrying a glass window upon which a transverse hair line is marked, or else it is provided with four indices arranged in a transverse straight line. The cursor enables the figures or graduations of the slide to be set readily against those on the fixed scales, and also enables any reading to be marked temporarily during the manipulations of the rule.

It may be added that the extreme left- and right-hand graduations of the scales are referred to as the left- and right-hand indices respectively.

Multiplication.

$$(a \times b \times c \ldots n = x)$$

It is obvious that although the figures on the scales start with unity, any multiple or submultiple of the value of 10 may be assigned to the indices provided that such value is adhered to throughout each complete operation. This holds good whatever be the nature of the calculation involved.

To multiply, the left-hand index of the slide is set to the multiplicand on the rule, and against the multiplier on the slide will be read the product on the rule. In this operation the length equivalent to the log of the first number is added to the length corresponding to the log of the second. Should there be more than two factors, the result of the first setting as above is not read, but the cursor is set thereto and the slide index brought up to the cursor setting, when the product is read as before, and so on to any number of factors. As continuous progression of the slide from left to right would bring the ultimate reading beyond the scale, it should be noted that the right-hand index may be used to set to the cursor; this will bring the product within the scale.

The number of digits, i.e. the position of the decimal point, may be evident from the factors. If such be not clear, however, it may be taken that the *sum* of the digits in the factors *less* the number of times the slide has been projected to the right will give the number of digits in the product. On some rules the cursor is provided with a movable index for registering the number of times the slide has been projected to the right.

Division.

$$\left(\frac{a}{b} = x\right)$$

This involves the *subtraction* of the logs of the numbers, therefore the process is exactly the reverse of multiplication, i.e. the divisor on the slide is set to the dividend on the rules, and against the index of the slide will be the quotient on the rule. The number of digits is found by *adding* the number of times the slide is projected to the right, to the *difference* between the divisor and dividend.

Proportion—Direct and Inverse.

$$\text{Direct } \left(a : b :: c : x, \text{ or, } c \times \frac{b}{a} = x\right)$$

Bring the first term on the slide to the second on the rule, move the cursor to the third on the slide, and read the fourth on the rule.

$$\text{Mean proportional } \left(\frac{a}{x} = \frac{x}{c}\right)$$

Set index on B to a on A, bring cursor to C on B; read under cursor x on D.

The procedure for inverse proportion is the same, save that the slide is *inverted*, so as to bring the A and C scales into juxtaposition.

Squares and Square Roots.

Squares and square roots are found by setting the cursor and reading from D to A or *vice versâ*.

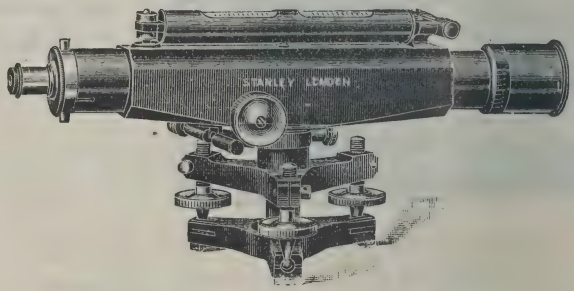
TRADE **STANLEY** MARK

English Drawing Instruments made throughout in our own factories by British labour.

SURVEYING and DRAWING INSTRUMENTS and every appliance for the CIVIL and MECHANICAL ENGINEER, ARCHITECT and SURVEYOR.

Please send for our 'L.11' Catalogue, post free.

W. F. STANLEY & CO. LTD.



Head Offices and Showrooms:—

286 HIGH HOLBORN, LONDON, W.C. 1

TRADE **STANLEY** MARK

The Largest Manufacturers of SURVEYING and DRAWING INSTRUMENTS in the World.

All our INSTRUMENTS are made throughout in our own factories, and are of the very highest quality.

Stanley's New Engineers' Level. With proper care will last in adjustment a lifetime.

Please send for our 'L.11' Catalogue, post free.

W. F. STANLEY & CO. LTD.

Head Offices and Showrooms :—

286 HIGH HOLBORN, LONDON, W.C.1

Cubes and Cube Roots.

Cubes and cube roots as well as all higher powers and roots are best found by the use of logs, which may be read on the back of the slide of most rules if the C index be set to the number whose log is required on D. The log is then multiplied or divided by the power involved. On certain rules the D scale is replaced by a log of a log scale designed by Professor Perry; this facilitates the finding of high powers and roots; thus

$a^n = x$; set the index on C to a on D; against or on C, read x on D.

$\sqrt[n]{a} = x$, or, $a^{\frac{1}{n}} = x$. Set n on C to a on D; against index on C, read x on D.

Sines and Tangents.

These may be found by setting the slide as in the case of the log of a number, the values being marked on the back of the slide with the log values.

On the back of most rules will be found a number of 'gauge points' useful for various special calculations.

For other and more extended applications of the slide-rule one of the many manuals specially devoted to the subject should be consulted, notably those by Blaine or Pickworth.

THE FULLER SLIDE-RULE.

(*W. F. Stanley & Co. Ltd.*)

For accurate calculations this is one of the best slide-rules invented. It is equal to an ordinary straight slide-rule 83 ft. 4 ins. in length, and its value can hardly be over-estimated. Those who have once become familiar with the instrument will never dispense with its use.

The rule (fig. 110) consists of a cylinder (*d*) that can be moved up and down upon, and turned round, an axis (*f*), which is held by a handle (*e*). Upon this cylinder is wound in a spiral a single logarithmic scale. Fixed to the handle is an index (*b*). Two other indices (*c* and *a*), whose distance apart is the axial length of the complete spiral, are fixed to the cylinder *g*. This cylinder slides in *f* like a telescope tube, and thus enables the operator to place these indices in any required position relative to *d*; *n* and *m* are two scales, the one on the piece carrying the movable indices, the other on the cylinder *d*.

This rule possesses advantages over the flat edge-to-edge form besides that of increased length of scale. The setting and reading are performed by indices, and not by scale against scale, and this is very much less troublesome. Also, multiplications and divisions containing a series of factors can be worked with the greatest facility, and as the logarithms of numbers by the use of scales *m* and *n* are easily read, the powers and roots of numbers are within the capacity of the instrument.

An additional improvement has now been effected in these rules, by adapting the case to support them when in use, thus overcoming the objection of being always obliged to hold them in the hand.

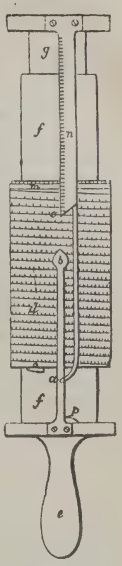


FIG. 110.

Rules for Instruments with one Fixed and two Movable Indices.

The fixed index will be denoted by F.
The top movable index will be denoted by A.
The lower ,, ,, ,, B.
When the indices are to be moved the term Set is used.
When the cylinder has to be moved the term Bring is used.

Multiplication.

$(a \times b)$
- Bring A to F
- Set A to 100
- Bring (*b*) to A or B
- Product read at F

$(a \times b \times c)$
- Bring (*a*) to F
- Set A to 100
- Bring (*b*) to A or B
- Set A to 100
- Bring (*c*) to A or B
- Product read at F

$(a \times b \times c \times d)$
- Bring (*a*) to F
- Set A to 100
- Bring (*b*) to A or B
- Set A to 100
- Bring (*c*) to A or B
- Set A to 100
- Bring (*d*) to A or B
- Product read at F

It will be seen that a similar sequence of operations applies to finding the product of any number of factors.

General Rule for the Number of Figures in the Product.

The *maximum* number of figures in the product is the algebraic sum of the number of figures in the factors, and this maximum results when all the factors (except the first) have to be brought to B. For each time a factor is brought to A, ONE is to be deducted from that sum.

So that if, during the operation, the number of times a factor has to be brought to A is noted, then the number of figures in the product is the sum of the number of figures in the factors (which is at once evident on inspection), less the number noted.

Thus, in the case of multiplying two factors together, the number of figures in the product is the sum or sum − 1, according as the second factor is brought to B or A.

Division.

$\frac{a}{m}$ { Bring (a) to F; Set A or B to (m); Bring 100 to A; Quotient read at F

$\frac{a \times b}{m}$ { Bring (a) to F; Set A or B to (m); Bring (b) to A or B; Quotient read at F

$\frac{a \times b \times c}{m}$ { Bring (a) to F; Set A or B to (m); Bring (b) to A or B; Set A to 100; Bring (c) to A or B; Quotient read at F

$\frac{a}{m \times n}$ { Bring (a) to F; Set A or B to (m); Bring 100 to A; Set A or B to (n); Bring 100 to A; Quotient read at F

$\frac{a \times b}{m \times n}$ { Bring (a) to F; Set A or B to (m); Bring (b) to A or B; Set A or B to (n); Bring (100) to A; Quotient read at F

$\frac{a \times b \times c}{m \times n}$ { Bring (a) to F; Set A or B to (m); Bring (b) to A or B; Set A or B to (n); Bring (c) to A or B; Quotient read at F

It will be seen that a similar sequence of operations applies to the division of the product of any number of factors by the product of any number of other factors.

General Rule for the Number of Figures in the Quotient.

The *maximum* number of figures in the quotient is the algebraic difference between the sum of the number of figures in the factors of the numerator and those of the denominator + (ONE) *for each factor of the denominator*, and this maximum results when A has to be set to *all* the factors of the denominator and all the factors of the numerator (except the first) brought to B.

One is to be deducted from the maximum number of figures each time B is set to a factor of the denominator or a factor of the numerator is brought to A.

So that if the number of times during the operation B is set to a factor of the denominator and a factor of the numerator is brought to A is noted, then the number of figures in the quotient is the maximum number of figures as found above (which is at once evident on inspection), less the number noted.

Thus, in the case of dividing one factor by another, the number of figures in the quotient is the difference or difference + 1, according as B or A is set to the divisor.

It should be remarked that the sequence of operations in *every case* is the same both for multiplication and division. The sequence of operations is :—First factor of numerator—First factor of denominator—Second factor of numerator—Second factor of denominator; and so on, commencing with the first factor of numerator at F, and ending by reading the quotient at F. If the above be written thus, this is at once evident.

$$a \times b = \frac{a \times b}{1}. \qquad a \times b \times c = \frac{a \times b \times c}{1 \times 1}. \qquad \frac{a}{m} = \frac{a \times 1}{m}.$$

$$\frac{a \times b \times c}{m} = \frac{a \times b \times c}{m \times 1}. \qquad \frac{a}{m \times n} = \frac{a \times 1 \times 1}{m \times n}. \qquad \frac{a \times b}{m \times n} = \frac{a \times b \times 1}{m \times n}.$$

This is important, as it is easy to remember. Also it will be seen, and should be remembered, that all factors of the numerator (except the first) are *Brought* to the movable index, and the movable index is *Set* to all factors of the denominator. Upon the upper movable index is marked - MUL., and on the lower one, - DIV. These are to remind the operator that when a factor of the numerator is *brought* to the upper index, and when the lower index is *set* to a factor of the denominator, 1 is to be deducted from the maximum number of figures that can occur in the result.

To Reduce Shillings to Decimals of a Pound.

Divide the number of shillings by 2 and point off one place. Thus 17 shillings ÷ 2 = 8·5 = £0·85.

To reduce pence to decimals of a pound multiply the pence by 4 for rough approximation and point off three places thus, 4 pence × 4 = 16 = £0·016. For accuracy multiply this last number by 4 and add the result with two figures overlapping to the right thus, 0·016 × 4 = 0·064. Then

0·016
064
0·01664

Any degree of accuracy can be reached by multiplying the last product by 4 and adding to the previous sum as before with two overlapping figures to the right, thus

$$\cdot 01664 + (064 \times 4) = \cdot 01664$$
$$256$$
$$\cdot 0166656$$

The absolute value of 4 pence is of course ·016. For purposes of the slide rule it is only needful at most, to go to the second multiplication, and this can be done mentally. Thus 5 pence is easily set down as £0·0208.

Conversions by the Slide-Rule—Gauge Points.

The application of the rule for problems involving proportion enables the implement readily to be used for conversions from values in one term to equivalent values in another. The following table, compiled from various sources, enables such conversions to be performed with accuracy. For instance, the circumference of any circle whose diameter is given may be read on the rule against the diameter on the slide if the value 226 on the slide is set to the value 710 on the rule, and so on.

Table of Gauge Points for Ordinary Slide-Rule.

Known Value on Slide.	Required Value on Rule.	Set to.	
		On Slide.	On Rule.
Circle, diameter	Circle, circumference	226	710
Circle, diameter	Circle, side of inscribed square	99	70

Horse-power per hour	Kilowatts (B.T.U.)	134	100
Watts	Horse-power.	5	·0067

The foregoing table is based on the assumption that the C and D scales of the rule are used. Certain values, however, cannot be read owing to the projection of the slide off the rule. If these be required, the cursor should be set to whichever index on C falls on the rule, and then the other index moved to coincide with the cursor line. If in this operation the slide be moved from left to right, the results must be multiplied by 10. If the slide be moved in the opposite direction the results should be divided by 10.

The A and B scales can be used conveniently if less accuracy is admissible. In this case the gauge points should be chosen on the left-hand side of the rule and the results read on the right and multiplied by 10.

SLIDE RULE CONSTANTS FOR BAR WEIGHTS.

If W = weight in lbs.; D = diam. in ins. of round bars; S = side in ins. of square bars; A and B = sides in ins. of rectangular bars; L = length in ins.; C = weight of 1 cub. in. of the material, then for

round bars, $W = \left(\frac{D}{e_1}\right)^2 L$; square bars, $W = \left(\frac{S}{e^2}\right) L$; rectangular bars, $W = \frac{AB}{e_3} L$;

in which e_1, e_2, and e_3 have the following values:—

Material.	Round Bars. e_1 (ins.).	Round Bars. e_1 (ft.).	Square Bars. e_2 (ins.).	Square Bars. e_2 (ft.).	Rectangular Bars. e_3 (ins.).	Rectangular Bars. e_3 (ft.).
Aluminium	3·71	1·071	3·29	0·950	10·82	0·903

(*C.A.P., in 'Machinery.'*)

Averaging Experimental Results.*

Arrange the results *in order of magnitude* and plot them at equal intervals along a base line, as in fig. 111, which represents the values of breaking tests of Portland cement made after 28 days in each case, the height of the base line being, for convenience, taken as 600 lbs. per

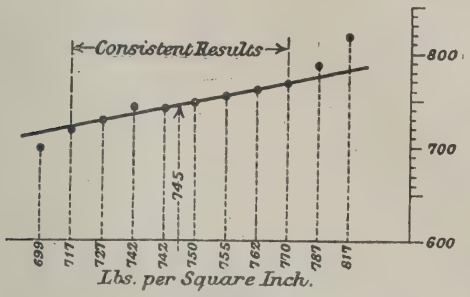

Fig. 111.

sq. in. It is now easy to draw a *straight* line through a large proportion of the dots with certainty as to its position, and to discard the discrepant values. The line will not usually be horizontal, though it would be so with experiments giving identical results. The centre of the line through the consistent results will give the mean height required, which in this case is 745 lbs. (or strictly 745·6 lbs.) per sq. in., instead of the arithmetical mean, which is 751·6.

$W = \frac{FL}{l}.$

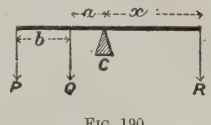

FIG. 190.

To find the fulcrum, C, when three forces act on one lever.

$Rx = Qa + P(b+a),$

$x = \frac{Qa + P(b+a)}{R}.$

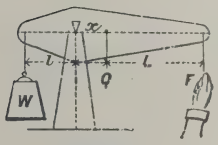

FIG. 191.

Q = weight of the lever.
x = distance from the centre of gravity of the lever to the fulcrum.

$F = \frac{Wl - Qx}{L},$

$W = \frac{FL + Qx}{l}.$

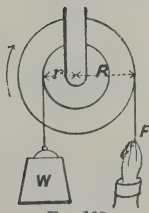

FIG. 192.

$F : W = r : R,$

$FR = Wr.$

$F = \frac{Wr}{R}, \quad R = \frac{Wr}{F},$

$W = \frac{RF}{r}, \quad r = \frac{RF}{W}.$

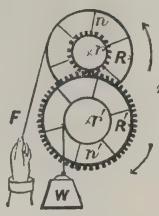

FIG. 193.

$F = \frac{Wrr'}{RR'}, \qquad W = \frac{FRR'}{rr'}.$

n, n' = numbers of revolutions of the wheels.

$n : n' = R' : r, \quad v : v' = RR' : rr'.$

v = velocity of F,

v' = velocity of W.

PULLEYS.

$\frac{v'}{v}$ = ratio of distances moved by W and F.

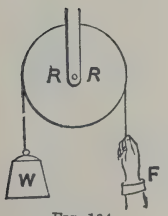

FIG. 194.

A single fixed Pulley.

$F : W = R : R,$

or $F = W.$

$\frac{v'}{v} = 1.$

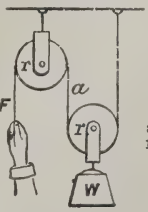

FIG. 195.

A single movable Pulley.

$F : W = r : 2r,$

or $F = \frac{1}{2}W.$

If the force F be applied at a and act upwards, the result will be the same.

$\frac{v'}{v} = 2.$

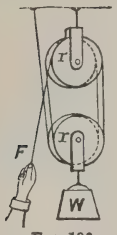

FIG. 196.

A double movable Pulley.

$F : W = r : 4r$,

or $F = \frac{1}{4}W$.

$\frac{v'}{v} = 4$.

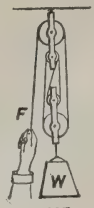

FIG. 197.

A double movable Pulley.

$F = \frac{1}{4}W$.

$\frac{v'}{v} = 4$.

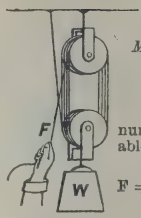

FIG. 198.

Multiple movable Pulley.

Let n = any number of movable pulleys, then

$F = \frac{W}{2n}$, $\frac{v'}{v} = 2n$.

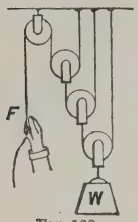

FIG. 199.

Compound Pulleys.

n = number of movable pulleys.

$F = \frac{W}{2^n}$, $W = 2^n F$,

$\frac{v'}{v} = 2^n$.

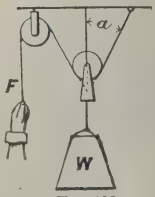

FIG. 200.

An oblique fixed Pulley.

$F : W = \sec \alpha : 2$.

$W = \frac{2F}{\sec \alpha}$, $F = \frac{W \sec \alpha}{2}$.

PARALLELOGRAM OF FORCES.

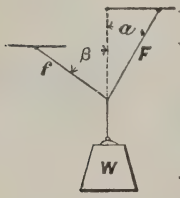

FIG. 201.

$W : F = \sin(\alpha+\beta) : \sin \beta$,

$W : f = \sin(\alpha+\beta) : \sin \alpha$.

$F = \frac{W \sin \beta}{\sin(\alpha+\beta)}$,

$f = \frac{W \sin \alpha}{\sin(\alpha+\beta)}$,

$W^2 = F^2 + f^2 - 2Ff \cos(\alpha+\beta)$.

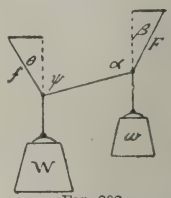

FIG. 202.

$F = \frac{w \sin \alpha}{\sin(\alpha+\beta)}$,

$f = \frac{W \sin \psi}{\sin(\psi+\theta)}$.

INCLINED PLANE.

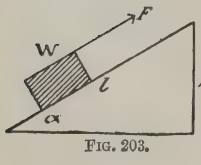

FIG. 203.

No Friction.

$F = \frac{Wh}{l} = W \sin \alpha$,

$W = \frac{Fl}{h} = \frac{F}{\sin \alpha}$.

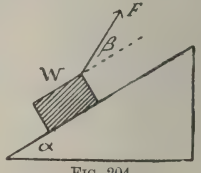

FIG. 204.

No Friction.

$F = W \frac{\sin \alpha}{\cos \beta}$,

$W = F \frac{\cos \beta}{\sin \alpha}$.

Friction.

$$F = W \frac{\mu \cos \alpha + \sin \alpha}{\mu \sin \beta + \cos \beta},$$

where μ = coefficient of friction.

$$F = W \frac{\sin(\phi + \alpha)}{\cos(\beta - \phi)},$$

where ϕ = limiting angle of resistance.

$\mu = \tan \phi$.

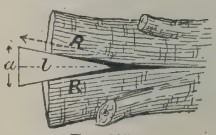

FIG. 205.

Wedge.

$F = \frac{Ra}{l}$,

$R = \frac{Fl}{a}$.

F = force required to drive the wedge.

Force Acting at an Angle.

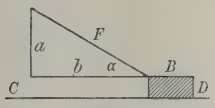

Fig. 206.

Let the line F represent the magnitude and direction of a force acting at an angle α to move the body B on the line CD; then the line a represents a part of F which presses the body B against CD, and the line b represents the magnitude of the force which actually moves the body B.

$$b = \sqrt{F^2 - a^2}, \quad b = F \cos \alpha.$$

Force by a Screw.

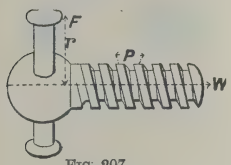

Fig. 207.

P = pitch of the screw (distance between threads).

r = radius on which the force F acts.

$\pi = 3{\cdot}1416$.

$$F : W = P : 2\pi r.$$

$$F = \frac{WP}{2\pi r}, \qquad W = \frac{F 2\pi r}{P}.$$

DYNAMICS.

Uniform Motion.

s = space passed through in time t. v = velocity.

$$s = vt.$$

FALLING BODIES.

Body Falling Freely.

s = space passed through in time t. v = velocity at end of time t.
g = coefficient of terrestrial acceleration = 32·2.

$$s = \tfrac{1}{2}gt^2. \qquad v = gt. \qquad v^2 = 2gs.$$

Body Thrown Downward.

If body is *thrown downward* with a velocity V,

$$v = V + gt. \qquad s = Vt + \tfrac{1}{2}gt^2. \qquad v^2 = V^2 + 2gs.$$

Body Thrown Upward.

If body is *thrown upward* with a velocity V,

$$v = V - gt. \qquad s = Vt - \tfrac{1}{2}gt^2. \qquad v^2 = V^2 - 2gs.$$

IMPACT OF BODIES.

The Bodies inelastic.

Fig. 208.

The Bodies move in the same direction.

$$v'(M+m) = MV + mv,$$

$$v' = \frac{MV + mv}{M+m}.$$

Fig. 209.

The Bodies move in opposite directions.

$$v'(M+m) = MV - mv,$$

$$v' = \frac{MV - mv}{M+m}.$$

Fig. 210.

Only one Body in motion.

$$v'(M+m) = MV,$$

$$v' = \frac{MV}{M+m}.$$

IMPACT OF BODIES.

The Bodies elastic.

$\left\{\begin{matrix} K = \text{coefficient of elasticity of } \frac{M}{m} \\ k = \quad " \quad " \quad : " \end{matrix}\right\}$

FIG. 211.

The Bodies move in the same direction.

$$V' = \frac{V(M - Km) + vm(1+K)}{M+m}.$$

$$v' = \frac{MV(1+k) + v(m - kM)}{M+m}.$$

FIG. 212.

The Bodies move in opposite directions.

$$V' = \frac{V(M - Km) - vm(1+K)}{M+m},$$

$$v' = \frac{MV(1+k) - v(m - kM)}{M+m}.$$

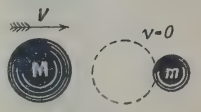

FIG. 213.

Only one Body in motion.

$$V' = \frac{V(M - Km)}{M+m},$$

$$v' = \frac{VM(1+k)}{M+m}.$$

ACCELERATION.

ACCELERATION PRODUCED BY A GIVEN PRESSURE.

If body (W lbs.) be on a perfectly smooth horizontal plane, and be acted upon by a pressure, P, acceleration, f, is

$$f = \frac{P}{W} g;$$

Where g = coefficient of terrestrial acceleration = 32·2.
If coefficient of friction on plane = μ.

$$f = \frac{P - \mu W}{W} g.$$

INCLINED PLANE.

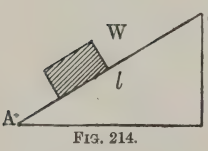

FIG. 214.

WORK ON AN INCLINED PLANE.

W = weight of body in pounds. μ = coefficient of friction.

Work in moving body from A to C = W ($\mu l + h$).
" " " C to A = W ($\mu l - h$).

WORK.

ACCUMULATED WORK.

W = weight of body. V = velocity.

$$\text{Work accumulated} = \frac{WV^2}{2g};$$

Where g = coefficient of terrestrial acceleration = 32·2.

If body changes its velocity from V to V_1,

$$\text{Work gained or lost} = \pm \frac{W(V^2 - V_1^2)}{2g}.$$

Accumulated Work.

(Continued.)

If a shot of weight P is fired into a mass of weight W with a velocity V,

$$\text{Work accumulated in shot} = \frac{V^2P}{2g}.$$

$$\text{Work lost} = \frac{PW}{2g(W+P)}V^2. \qquad \text{Work remaining} = \frac{V^2}{2g}\cdot\frac{P^2}{W+P}.$$

Gravity.

g = acceleration in centimetres per second due to gravity. l = length of seconds pendulum in centimetres.

Values of g in various Localities.

Place.	Latitude.	g.	l.
Equator	°	978·1	99·103
Greenwich	51·29	981·17	99·413
Paris	48·50	980·94	99·39
Berlin	52·30	981·25	99·422
Dublin	53·21	981·32	99·429
Glasgow	55° 52′ 42·″8	981·44	99·442
Edinburgh	55·57	981·54	99·451
N. Pole	90°	983·11	99·61

THE PENDULUM.

Simple Pendulum.

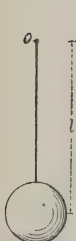

Fig. 215

l=length of pendulum in inches. t=time in secs. of one oscillation (the time of moving from the highest point on one side to the highest point on the other). g=coefficient of terrestrial acceleration at equator=32·097 ft. per sec.=385·163 ins. per sec. π=3·1416.

$$t = \pi\sqrt{\frac{l}{g}} = 3{\cdot}1416\sqrt{\frac{l}{385{\cdot}163}} = \frac{\sqrt{l}}{6{\cdot}247}.$$

Length of seconds pendulum at equator=39·0265 ins.

If L=latitude,

$$l = 39{\cdot}0265 + {\cdot}1608\sin^2 \text{L, for a 1-second pendulum.}$$

Compound Pendulum.

Fig. 216.

o = centre of suspension. l = equivalent length of simple pendulum to give the same time of oscillation. W = weight of lower bob. w = weight of upper bob.

Fig. 216, $l = \dfrac{a^2W + b^2w}{aW - bw}$; Fig. 216A, $l = \dfrac{a^2W + b^2w}{aW + bw}$.

The length is actually the distance of the *centre of suspension* from the *centre of oscillation* (this is the same as the *centre of percussion*), the *centre of oscillation* being that point at which, if all the matter were collected, the time of oscillation would remain unaltered.

In case fig. 216A, if w = W, then rate of oscillation will be greatest if w is put in such a position that $b = (\sqrt{2} - 1)a$, in which case $l = 2(\sqrt{2} - 1)a$.—*H.R.K.*

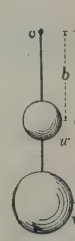

Fig. 216A.

Conical Pendulum.

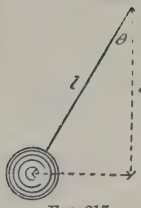

Fig. 217.

t=time of one revolution, g=coefficient of terrestrial acceleration = 32·2, π=3·1416.

$$t = 2\pi\sqrt{\frac{a}{g}}.$$

This formula is correct irrespective of the length, l, of the rod (fig. 217).

Governor of Steam Engine.

θ = angle (fig. 217) corresponding to a given period of rotation, t, g = coefficient of terrestrial acceleration = 32·2, π = 3·1416.

$$l = \frac{t^2 g}{4\pi^2 \cos\theta}.$$

CENTRE OF OSCILLATION OR PERCUSSION.

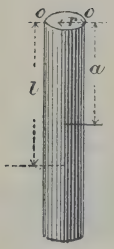

Fig. 218.

The *Centre of Oscillation* is that point in a vibrating body where, if all the matter were collected, the time of vibration would be unchanged.

The *Centre of Percussion* is that point in a revolving body at which, upon the point striking against an immovable obstacle, the whole of the motion of the body is destroyed. The centres of oscillation and percussion are the same.

o = centre of suspension. r = radius of cylinder. a = half length.

$$l = \frac{16a^2 + 3r^2}{12a} = \frac{4a}{3} + \frac{r^2}{4a}.$$

If r is small,

$$l = \frac{4a}{3}$$

i.e. in a bar the centre of oscillation or percussion is at a point distant from the centre of suspension two-thirds of the *total* length of the bar.

CENTRIFUGAL FORCE.

F = *Centrifugal Force*, in pounds.
M = the *Mass* or weight of the revolving body, in pounds.
v = *Velocity* of the revolving body, in feet per second.
R = *Radius* of the circle in which the body revolves, in feet.
n = number of *Revolutions* per minute.
g = coefficient of terrestrial acceleration = 32·2. π = 3·1416.

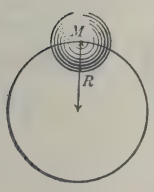

Fig. 219.

$$F = \frac{Mv^2}{gR} = \frac{Mv^2}{32{\cdot}16R}. \qquad F = \frac{4MR\pi^2n^2}{60^2g} = \frac{MRn^2}{2933}.$$

$$M = \frac{FgR}{v^2} = \frac{2933F}{Rn^2}. \qquad R = \frac{Mv^2}{Fg} = \frac{2933F}{Mn^2}.$$

$$n = \sqrt{\frac{2933F}{MR}}. \qquad v = \sqrt{\frac{FRg}{M}}.$$

Fig. 220.

Centrifugal force of a ring.

$$F = \frac{Mn^2\sqrt{R^2 + r^3}}{4150}.$$

Fig. 221.

Centrifugal force of a grindstone, circle-plane, cylinder, rotating round its centre.

$$F = \frac{MRn^2}{4150}.$$

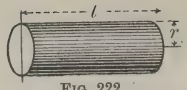

FIG. 222.

Centrifugal force of a cylinder rotating round the diameter of its base.

$$F = \frac{Mn^2\sqrt{4l^2 + 3r}}{10260},$$

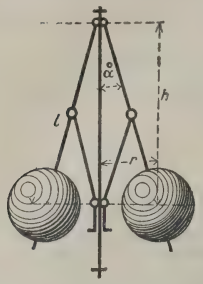

FIG. 223.

Governor.

$$n = \frac{60}{2\pi}\sqrt{\frac{g}{h}} = \frac{54{\cdot}16}{\sqrt{h}} = \frac{54{\cdot}16}{\sqrt{l\cos a}},$$

$$h = \frac{2933}{n^2}, \quad l = \frac{2933}{n^2\cos a} = \frac{h}{\cos a},$$

$$\cos a = \frac{2933}{n^2 l} = \frac{h}{l}, \quad r = \sqrt{l^2 - h^2}.$$

RADIUS OF GYRATION.

The *Centre of Gyration* is that point at which, if all the revolving matter were collected, it would obtain equal angular velocity from, and sustain equal resistance to, the force that gives the rotary motion. The *Radius of Gyration* (x) is the distance of the centre of gyration from the axis, A.

MOMENTS OF INERTIA.

If each element of the mass of any solid body be supposed to be multiplied by the square of its perpendicular distance from a given line or axis, the sum of all these products is called the moment of inertia of the body with respect to that axis. The following Table gives the most useful cases :

M = mass of the body. I = moment of inertia.

Uniform thin rod, axis at end, length = l . . . . . $I = M\frac{l^2}{3}$.

" " " through middle, length = l . . . . . $I = M\frac{l^2}{12}$.

Rectangular lamina, axis through centre and parallel to one of sides, a and b lengths of sides, a the side bisected . . . . . $I = M\frac{a^2}{12}$.

Rectangular lamina, axis through centre and parallel to one of sides, a and b lengths of sides, b the side bisected . . . . . $I = M\frac{b^2}{12}$.

Rectangular lamina, axis through centre and perpendicular to the plane, a and b lengths of sides . . . . . $I = M\frac{a^2 + b^2}{12}$.

Rectangular parallelopiped, axis through centre and perpendicular to a side, a, b, and c lengths of sides :

1. Axis perpendicular to side contained by a and b . . . . $I = M\frac{a^2 + b^2}{12}$.

2. „ „ „ „ a „ c . . . . $I = M\frac{a^2 + c^2}{12}$.

3. „ „ „ „ b „ c . . . . $I = M\frac{b^2 + c^2}{12}$.

Circular plate, axis through centre perpendicular to the plate, radius $= r$. $I = M\frac{r^2}{2}$.

Circular plate, axis any diameter, radius $= r$ . . . . . $I = M\frac{r^2}{4}$.

Circular ring, axis through centre perpendicular to plane of ring, outer radius $= R$, inner radius $= r$ . . . . . $I = M\frac{R^2 + r^2}{2}$.

Circular ring, axis any diameter . . . . . $I = M\frac{R^2 + r^2}{4}$.

Right cylinder, axis the axis of figure, r = radius of section . . . $I = M\frac{r^2}{2}$.

Right cylinder, axis through centre perpendicular to axis of cylinder of length, l . . . . . $I = M\left(\frac{l^2}{12} + \frac{r^2}{4}\right)$.

Hollow cylinder, axis the axis of figure, outer radius $= R$, inner radius $= r$. $I = M\left(\frac{R^2 + r^2}{2}\right)$

Right cone, axis the axis of figure, r = radius of base . . . . . $I = \frac{3}{10}Mr^2$.

Sphere, axis any diameter, r = radius . . . . . $I = \frac{2}{5}Mr^2$.

ENERGY OF A ROTATING BODY.

The energy of a rotating body $= \frac{1}{2}\omega^2 I$, ω being the angular velocity, and I the moment of inertia.

BALLISTIC PENDULUM.

W = weight of pendulum. P = weight of a shot fired into W. V = velocity of shot. θ = angle through which pendulum moves. n = number of vibrations per minute pendulum makes. a = distance from centre of suspension of point at which shot enters block. h = distance of centre of gravity of pendulum weight with shot in it from centre of suspension. g = coefficient of terrestrial acceleration = 32·2. $\pi = 3{\cdot}1416$.

$$V = \frac{W + P}{P} \frac{120g \sin \frac{\theta^\circ}{2}}{\pi n} \frac{h}{a}$$

BRAKES FOR POWER MEASUREMENT.

Hirn's Rope Brake.

A convenient form of brake for power measurement is one consisting of a band of rope enveloping the fly-wheel of the engine being measured.

Fig. 237, p. 127, represents the rope brake as arranged by Mr. B. H. Thwaite for the purpose. It consists of a band of rope carrying five wood blocks, with side flanges to hold the brake on the wheel. Each end of the rope is attached to a spring balance.

The net pull upon the wheel rim is the difference of the two spring balance readings, and the power developed by the engine is

$$(W - w) \times D\pi \times N \div 33{,}000 = \text{B.H.P.},$$

Where

W = the reading of the large balance or the pull in pounds.
w = the reading of the small balance or the pull in pounds.
D = the diameter in feet of the rim on which the brake lies.
N = revolutions per minute.
B.H.P. = brake horse-power.
$\pi = 3{\cdot}1416$.

The results of the formula are slightly below the actual power, owing to the brake belt not being absolutely flexible. French engineers measure D at the centre of the rope thickness, an error perhaps slightly in the other direction.

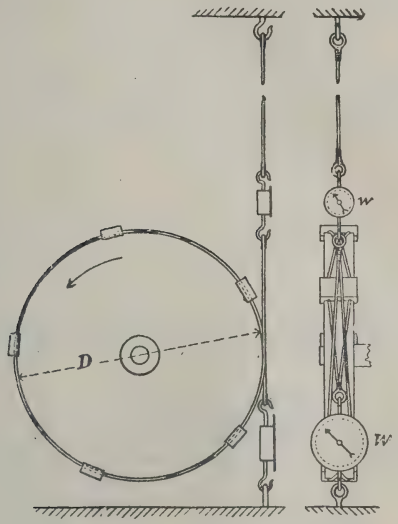

FIG. 237.

For the large spring balance a weight may be substituted.

A rope brake never sticks, nor does it ever suddenly lose its grip.

The Prony Brake.

This form of brake is not now much used, but it is useful for small power measurements. In its simple form, fig. 238, it consists of a couple of wooden blocks clipped upon the pulley or shaft

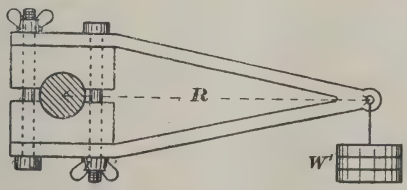

FIG. 238

transmitting the power to be indicated. Attached to the blocks is a lever, to which is hung a scale pan or a spring balance. The diameter D in the formula for Thwaite's brake is, in the case of the Prony brake, double the radius R measured to the point of suspension of the pan, and $W - w$ is the weight W'.

The difficulty with the Prony Brake is the constant vibration of the weighted arm. The

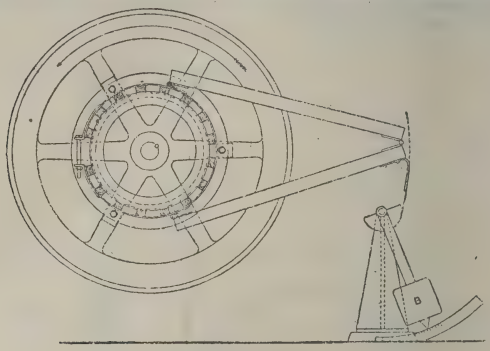

FIG. 239.

difficulty has been reduced at Purdue University by the addition of a pendulum lever weight, B (fig. 239), the quadrant of which may be divided by actual weight determination.

Ringelmann's Brake.

In the brake of M. Ringelmann (fig. 240) the brake band is a strap of iron, on which, by a hook, C, is suspended a weight, Q. If the wheel runs faster and lifts the weight, the hook travels in the direction of the arrow, and *vice versa*. The brake is in two halves, A and B, joined by a tightening screw at V, and by a peculiar joint at E, shown enlarged in fig. 241. The sector, S S, which carries the ends of the brake straps, is held by a pair of cords, *mas* and *s'bnp*, the first fixed to a regulating roller, *m*, attached to the floor; the

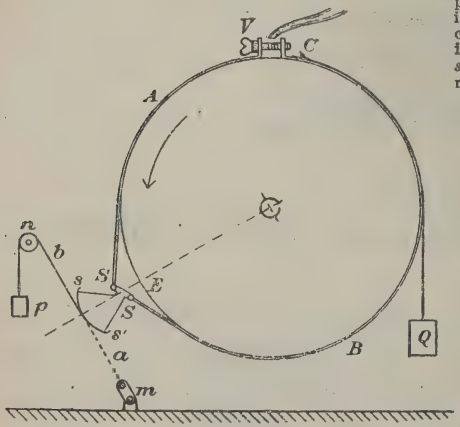

FIG. 240.

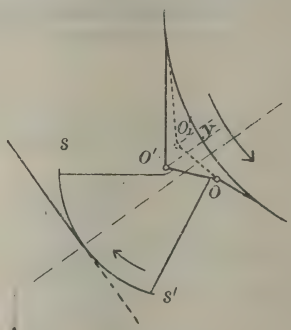

FIG. 241.

second to a small weight, *p*, over a pulley, *n*. The mean position of the sector is as shown, the cords *b* and *a* being in one straight line. If in the course of a test the brake is pulled round, the point O (fig. 241) is lowered, the sector rolls on the cord, and the point O' comes to O',, lengthening the brake strap by the amount *y*. Soap and water is kept flowing on at the point V. The tension of the brake is thus maintained to a constant power, and the lubrication is also constant, so that the motor is compelled to exercise a constant power. This brake was used for the testing of small motors at Meaux by M. Ringelmann in 1894.

Hydraulic Brake.

Professor Reynold's hydraulic brake consists of a fan working inside a cylindrical casing of water. A weighted arm is attached to the casing, and measures the work absorption just as in the rope brake. Water is continually run through the casing, and comes out at a higher temperature, and the rise in temperature may be used as an approximate check upon the power if the quantity of water be known and its rise of temperature noted.

Water-pipe Absorption Dynamometer.

In place of ropes the encircling band may be made of flexible water-pipes, the rim being of wood. Water is circulated through the pipes to keep them cool. Each band of $\frac{3}{8}$ in. iron pipe on

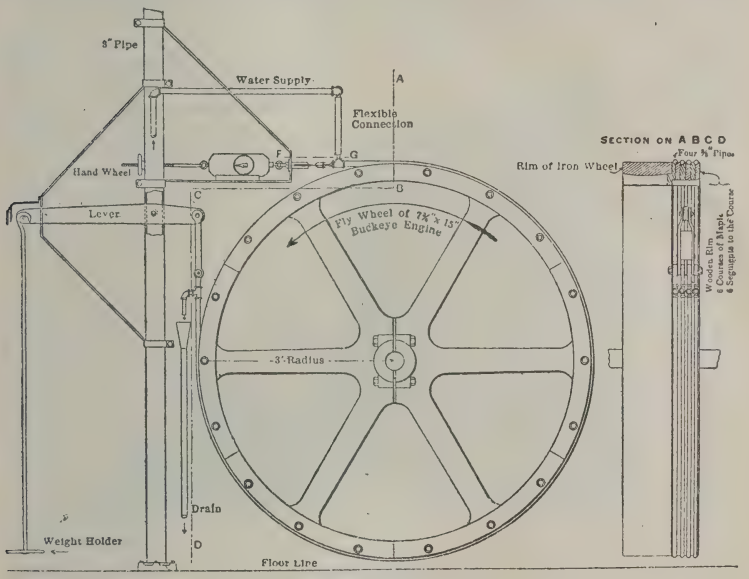

FIG. 242.

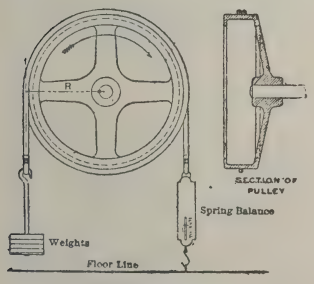

FIG. 243.

a 6 ft. wooden rim will absorb 10 horse-power at 150 revolutions. Fig. 242, as used at Purdue University, shows a brake of this description.

Cooling Brake Rims.

In many cases the inside of a brake rim is of trough form (fig. 243), which will hold water when revolving, by virtue of the centrifugal action. The trough being filled with water is kept to (at most) 212° F. by the evaporation of the water, which is kept constantly running into the rim in a small stream.

Another means of cooling is to encircle a sheet-steel brake band with iron wire netting, which holds by capillary action water poured on it; this evaporates and cools the strap. Surplus water runs off at the bottom of the band.

The Alden Brake.

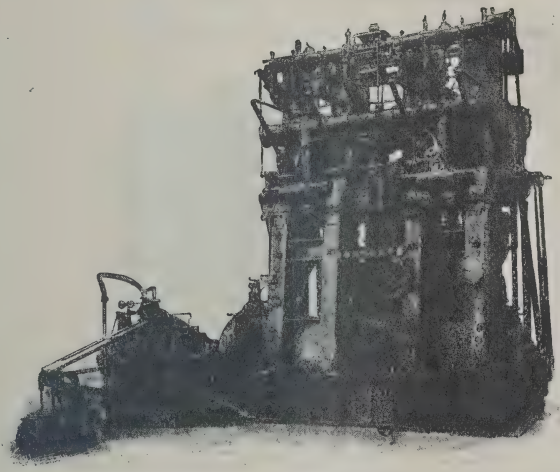
This brake consists, for 200 horse-power, of a 56-inch disc of cast iron revolving between two plates of copper, containing cylinder oil, which is circulated from the circumference towards the centre. Outside the copper plates water circulates at about 15 lbs. pressure, and serves both to cool the plates and maintain contact pressure on the moving disc. By circulating more water the brake resistance may be sensibly increased through the diminished viscosity of the oil, and *vice versa*. This brake is said to run for hours at great constancy, and to be nearly perfect in its action.

The Brotherhood Fluid Friction Dynamometer.

This arrangement (*Peter Brotherhood Ltd., Peterborough*) is specially suitable for high and moderate speed testing. All power given to the machine is recorded accurately; no losses in shaft bearings, etc., have to be allowed for, as the friction of bearings is measured by the dynamometer and included in the readings; no calibration is required. Calculations involve simple multiplication only from the direct readings of a spring balance or weighing machine; no clutch is required. Motors under test may be started up with the brake set for full loads, the torque at the lowest speeds being extremely small and rising rapidly as the normal speed is reached. The resistance rises very rapidly with increase of speed and also diminishes rapidly with decrease in speed, so that the brake is self-governing, and any sudden increase in friction is impossible. The machine is extremely accurate, the only power not recorded being the infinitesimal friction between the casing and its supporting roller bearings. The casing rests freely on the rollers, and motion at the supports only occurs when the load is changing, and is then very small, so that no measurable energy is absorbed. The constants may be verified by use of a rule and standard weights only, the only factors being the distance from the shaft centre to the point of application of the spring balance, and the readings of the spring balance which may be directly tested by deadweights. This feature enables the user to check the readings immediately before and after each test if desired.

The principle employed is that of the frictional resistance between fluids and rotating plates. Several perforated annular plates are secured to the casing of the brake, and between each pair a disc rotates with the shaft. The rotating discs run near the fixed plates, but do not touch them. On the introduction of water or other fluid into the casing, friction is set up between the fluid and the plates. The moment of the frictional resistance between the fluid and the fixed plates is measured by means of a spring balance acting at a convenient radius, the casing being free to rotate within limits on trunnions and anti-friction rollers. A platform weighing machine may be substituted for the spring balance if preferred. The energy delivered to the dynamometer is transformed by fluid friction into heat which is absorbed by the fluid; as no solid friction occurs, unequal heating and seizing of surfaces cannot arise. The quantity of water flowing through the dynamometer need be only sufficient to absorb the power and keep the temperature down to the desired limits. For example, when absorbing 100 b.h.p., assuming that the temperature of the water supply is 60°F., and that the water is raised to 160°F. before leaving the casing, about 5 gallons per minute would be sufficient. This water enters and leaves the casing quietly—no water is splashed about. The load on the motor at any desired speed can be quickly and smoothly adjusted by varying the amount in the casing; any desired quantity of water may be retained, and therefore any load may be steadily maintained, although water is flowing through continuously. For short tests sufficient water may be placed in the casing, and no continuous flow provided. This feature is of great use in comparing and calibrating motors, engines, etc. With these dynamometers a constant and definite torque resistance will always be obtained at any given speed and with a definite quantity of water in the casing. It is thus easy to adjust the machine to give a predetermined load curve. This feature has been found of great value in testing engines for marine propulsion, the dynamometer resistance varying with speed proportionally in precisely the same way as the speed and power of a marine propeller varies.

The Froude Water Dynamometer.



This dynamometer (*Heenan & Froude Ltd., Worcester*) is made in two types, viz.:—

1. The 'Standard Dynamometer,' which is used for testing all types of engines at a constant speed, such as large gas engines, Diesel engines, or steam turbines.

2. The 'Sluice Gear Dynamometer,' which is used for testing high-speed petrol engines where the speed varies over a very large range.

The Standard machine consists of a rotor revolving in water contained in the casing; the latter is suitably mounted on anti-friction rollers and connected to a water supply. The rotor is fixed on a shaft which projects on either side of the casing and to which the engine or motor to be tested is coupled. Each face of the rotor is formed with a semi-elliptical annular channel divided into a number of compartments by oblique vanes as shown in fig. 244. The corresponding

faces of the casing are formed of similar channels divided in the same way. The channels on the rotor and the casing thus form two complete annular channels of elliptical cross-section, each channel being divided into compartments by means of the oblique vanes. When in action the water in each annular channel is rotated continuously by the forces imparted to it by the rotor, and passes from one compartment into the next, and so on. An extremely high speed of rotation of the water is obtained, and the power put into the dynamometer is, by the hydraulic friction, converted into heat which passes away in the water issuing from the machine. The motion of the water causes the rotor to re-act on the casing, which tends to turn on its supporting

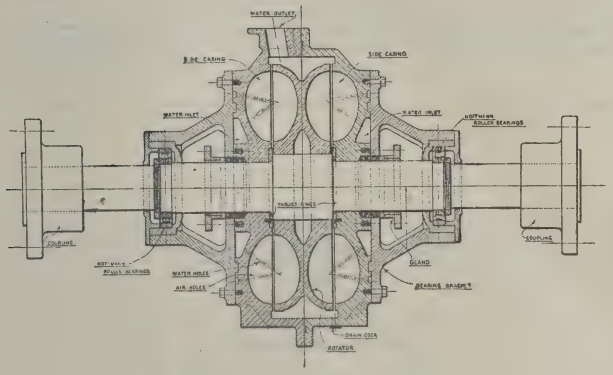

FIG. 244.

rollers; this is prevented by means of an extension arm at the end of which are suspended a number of balance weights. These weights are arranged to re-act upon the power-absorbing portion of the apparatus in such a way that they are kept suspended in mid-air, and thus represent the net weight which is being lifted by the balance-arm at a given radius. The torque is thus known and from it the horse-power is obtained by a simple formula. An automatic valve for controlling the flow of water through the machine is mounted on the outlet from the casing. The balance weights tend to depress the arm, which by an arrangement of valve gear causes the automatic valve to choke back the flow of water and thereby maintain a lifting effort sufficient to keep the weights floating. A lever is fitted for the purpose of quickly throwing the load on or off. The rollers supporting the casing are mounted on ball bearings, so that the machine is very sensitive in its action. As the friction of the dynamometer shaft in the glands, as well as other solid and hydraulic friction, all react on the casing, no error is introduced on this account.

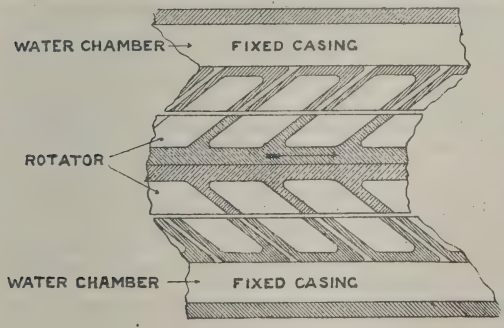

FIG. 245.

In the Sluice Gear type of dynamometer the rotor and casing are constructed on similar lines to the Standard machine, but the method of controlling the power absorbed by the dynamos meter is different. In this machine the casing is always full of water, and the output is varied by inserting plates, or sluices, between the rotor and casing. These sluices are operated by a hand wheel placed in a suitable position as shown in fig. 245. As this machine can absorb a

very large range of powers at any particular speed, it is suitable for testing high-speed petrol engines, with the following advantages :—

(1) Should the engine falter, the load automatically falls off, and it is thus given an opportunity to pick up again. (2) The power absorbed by the brake can be altered while running, by turning a single hand-wheel. (3) No resistance is offered at the starting-up : the engine, therefore, can be stopped and restarted without altering the adjustment of the brake. (4) The rotating parts are comparatively light, and have little momentum, so that the machine can be stopped very quickly should this be necessary on account of engine trouble. (5) No attention need be paid to the brake while carrying out tuning-up adjustments. The tester may adjust the carburettor, ignition, etc., without altering the setting of the sluice-gear control, and any increase in output will be automatically registered on the spring balance.

To measure the torque exerted on the casing, a spring balance is fitted at the end of the arm, so that the pull can be read direct. The horse-power is calculated from the formula :—

$$\text{B.H.P.} = \frac{\text{W} \times \text{N}}{\text{K}},$$

where W = the load on the arm in lbs. ; N = revolutions per minute ; K = constant.

The Fan Dynamometer.

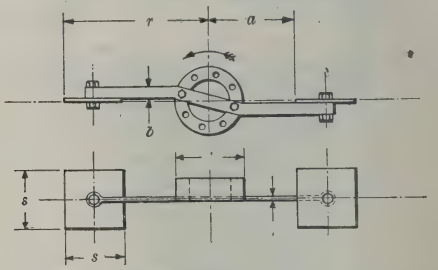

FIG. 246.

If w = torque driving the fan in inch-lbs ;
w_b = resisting torque due to the blades alone ;
w_a = " " " arms "
N = revs. per min. of the fan ;
s = length of side of square blades or diameter of round blades in inches
r, a, b, t, and c are other dimensions in inches ;
W = density of the fluid in which the fan rotates, in lbs. per cubic foot,
= 62·33 for water at 50° F. $= \frac{1{\cdot}317 \times \text{barometric pressure in inches of mercury}}{460 + \text{temp. in } ^\circ\text{F.}}$;
H.P. = horse-power absorbed by fan ;
K = a coefficient depending upon the value of r/s and upon the shape of the blade; see values tabulated below for square and circular blades having square edges.

Values of r/s	2·5	3·0	3·5	4·0	4·5	5·0	5·5	6·0	6·5	9·0	12·0
K for circular blades	1·69	1·69	1·66	1·63	1·60	1·59	1·58	1·575	1·575	1·575	1·575
K for square blades	2·25	2·28	2·24	2·18	2·16	2·12	2·10	2·08	2·04	2·04	2·04

σ = a coefficient depending upon the ratio b/t.

Values of b/t	2	3	6
Values of σ	1·3	0·94	0·62

Then :—
$w_a = 0{\cdot}35 \times 10^{-8}\sigma\text{N}^2a\text{W}$; $w_b = \text{KN}^2r^3s^2\text{W}$: $w = w_a + w_b$*; H.P. $= w\text{N}^3/3{,}6000$.

* For this relation to hold, t must be less than $\frac{s}{7}$

Notes on the Fan Dynamometer.

Care should be taken that the arms and fastenings are amply strong enough to withstand the centrifugal stresses. For reasonably accurate work, with fans rotating in air, one side of the fan should be completely free from obstruction for a distance of at least '3 *r*' inches from the plane of rotation, and on the other side 'C' should not exceed '*a*.' Also the floor should be distant at least '*r*' inches. The linear velocity of the centre of the blades must not exceed, say, 350 ft. per second. In order to compute W with accuracy, the barometric pressure, and the temperature of the air at the periphery of the fan should be taken. Fans rotating in water must have at least as much clearance around them as is specified above, and must not be rotated at such a speed as to produce cavitation. To facilitate work in the test-shop the 'H.P., Rev.' curves for each blade used should be plotted on logarithmic paper for some standard value of W. Since the H.P. varies approximately as N^3, N should be observed with great accuracy—a speedometer is usually not sufficiently accurate.

See also Hodgson, *Proc. Inst. Automobile Engineers*, March 1916.

(*J. L. Hodgson.*)

The Torsion Meter.

(*Hopkinson-Thring Patent.*)

The Hopkinson-Thring Torsion Meter (*Messrs. Siemens Bros. & Co. Ltd.*) has been designed for determining the power transmitted by turbine and other shafts. It requires only a very short length of shaft, is extremely compact and strong, and it gives a direct reading of the torsion on the shaft. The zero point of the apparatus can readily be ascertained by barring the shaft. The instrument offers also a simple means of determining the friction of the shafts themselves.

The principle of the apparatus consists in the observation of the twist between two adjacent points on the shaft by means of two beams of light projected on to a scale from a fixed and a movable mirror.

A diagrammatic arrangement of the complete apparatus is shown in end elevation and plan in fig. 247. A collar R, clamped to the shaft of which the torque has to be measured, is provided with a flange projecting at right angles to the shaft and an extension. A sleeve T, provided with a similar flange and extension at one end, is clamped at its further end on to the shaft in such a manner that its flange is close to that on the collar R, whilst its extension overlaps that of the collar R, on which it is supported to keep it concentric. Both the collar and sleeve are quite rigid, so that when the shaft is twisted by the transmission of power the flange on the sleeve T will move relatively to that on the collar R, the movement being equal to that between the two parts of the shaft on which these fittings are clamped. This movement is made visible by one or more systems of torque mirrors mounted between the two flanges, which reflect a beam of light, projected from a lamp, on to a scale divided in a suitable manner on ground glass.

Each system of torque mirrors consists of a mounting, pivoted top and bottom on one or other of the flanges, in which two mirrors are arranged back to back. This mounting is provided with an arm, the end of which is connected by a flat spring to an adjustable stop on the other flange. Any relative movement of the two flanges will turn the torque mirror and thereby cause the beam of light to move on the scale, the deflection produced being directly proportional to the torque applied to the shaft. Hence, if the rigidity of the material and the number of revolutions per minute are known, the h.p. transmitted can be arrived at immediately.

With the arrangement described, a reflection will be received from each mirror at every half revolution of the shaft; but where the torque varies during a revolution (as with reciprocating engines), a second system of mirrors may be arranged at right angles to the first system, so that four readings can be taken during one revolution; or, if two scales are used, eight readings can be taken.

Fig. 248 shows how the beam of light reflected by the mirror when in its highest position passes through the upper part of the scale; while the second reflection will occur when the mirror is in the position occupied by the zero mirror, the beam of light passing through the lower part of the scale. The position of the torque mirror in fig. 248 is such that if the reflected beam strikes the scale to the right of the zero line, when the shaft has made a further half revolution, the reflected beam from the other mirror will strike the scale to the left of the zero line.

The fixed mirror is attached to one of the flanges (in fig. 247 to the flange of the sleeve T). This must be adjusted so that the beam of light reflected from it is received at the same point on the scale as those from the movable mirrors when there is no torque on the shaft. To facilitate the erection and adjustment of the apparatus, the box containing the scale and carrying the lamp is fitted with trunnions, so that it can be inclined as required.

HOPKINSON-THRING TORSION METER.

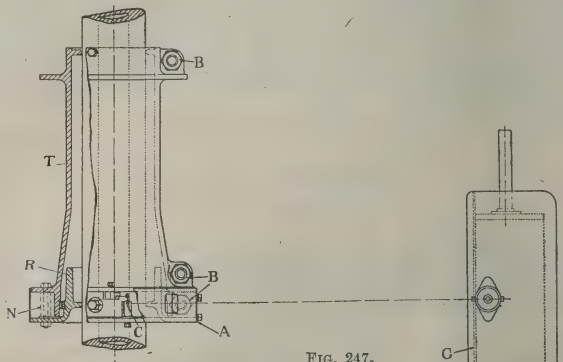

FIG. 247.

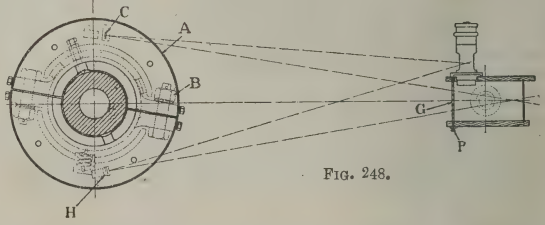

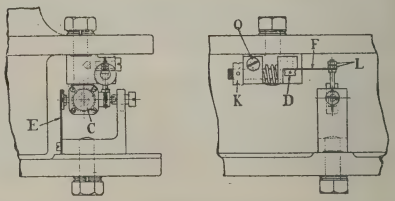

FIG. 248.

If the position of the apparatus on the shaft becomes altered relatively to the scale, owing to the warming up of the shaft or from other causes, this is indicated immediately to the observer by an alteration in the position of the zero as reflected by the fixed mirror. Hence the scale zero may be adjusted, if desired, by moving the scale so that its zero coincides with the reflection from the fixed mirror, but this is not necessary to obtain a correct result, since the mean of the two readings will be the same. It will readily be understood that, as a movement of the torque mirrors can only occur through a relative movement of the two flanges, the vibration of the shaft or of the ship will not influence the readings in any way.

The apparatus is made in seven standard sizes, to fit shafts from 1 up to 21 inches in diameter, the overall length of the meters being 13½ to 58¼ inches. All sizes have been in practical operation for a considerable time, with entirely satisfactory results, in warships and other turbine-driven steamers, running at speeds up to 1,500 revolutions per minute. The smaller sizes of the instrument are designed to run up to 3,000 revolutions per minute.

ANIMAL POWER.

MEN.

The mean effect of the power of a man, unaided by a machine, working to the best practicable advantage, is the raising of 70 lbs., 1 foot in a second, for 10 hours in a day.

Two men, working at a windlass with the handles at right angles to each other, can raise 70 lbs. more easily than one man can 30 lbs.

A man of ordinary strength exerts a force of 30 lbs., for 10 hours in a day, with a velocity of 2½ feet per second = 4,500 lbs. raised 1 foot in a minute = ·2 of the work of a horse.

A man can travel, without a load, on level ground, during 8½ hours a day, at the rate of 3·7 miles an hour, or 31½ miles a day. He can carry 111 lbs. 11 miles in a day.

A porter going short distances, and returning unloaded, can carry 135 lbs. 7 miles a day. He can transport, in a wheelbarrow, 150 lbs. 10 miles in a day.

WEIGHT OF CROWDS.

Experiments carried out by Professor L. J. Johnson, of Harvard University, show that it is possible for this to reach the high figure of 181·3 lbs. per square foot of floor surface. If the crowd jumps, the apparent load may be 50 per cent. more than the steady load, and running four abreast will show a similar result. A weight of 140 lbs. per square foot is quite possible where there are throngs of people; while a load of 80 lbs. per square foot is quite common in buildings and private houses where social gatherings are frequent, and a maximum of 40 lbs. or 45 lbs. is far short of what actually does prevail.

HORSES.

A horse can travel 400 yards, at a walk, in 4½ minutes; at a trot, in 2 minutes; and at a gallop, in 1 minute. A draught horse can draw 1,600 lbs. 23 miles a day, weight of carriage included. The ordinary work of a horse may be stated at 22,500 lbs., raised 1 foot in a minute, for 8 hours a day. In a horse-mill a horse moves at the rate of 3 feet in a second. The diameter of the track should not be less than 25 feet. A horse can exert a horse-power hour for but six hours a day. One machinery horse-power is equivalent to that of 4½ horses. The strength of a horse is equivalent to that of 5 men.

TABLE OF THE AMOUNT OF LABOUR A HORSE OF AVERAGE STRENGTH IS CAPABLE OF PERFORMING, AT DIFFERENT VELOCITIES, ON CANALS, RAILROADS, AND TURNPIKES.

4	4·5	102	72	9·0	8	1·125	12·8	36·0	4·5
5	2·9	52	57	7·2	10	0·750	6·6	28·8	3·6

A horse in a mill can produce an effect of 106 lbs., at a velocity of 3 feet in a second, for 8 hours in a day. A mule can produce, under a like velocity and time, an effect of 71 lbs.; and an ass, 37 lbs.

An ox, walking at a velocity of 2 feet in a second (1·34 miles per hour) will exert a pull of 154 lbs. for 8 hours in a day.

The draught of man and animals by traces is as follows:

Man, 150 lbs. | Horse, 600 lbs. | Mule, 500 lbs. | Ass, 360 lbs.

A man rowing a boat 1 mile in 7 minutes performs the labour, while rowing, of 6 fully-worked labourers at ordinary occupations of 10 hours.

The force of traction on a railroad or turnpike is constant, but the mechanical power necessary to move the carriage increases as the velocity.

Labour upon Embankments.

Single Horse and Cart.—A horse with a loaded dirt-cart, employed in excavation and embankment, will make 100 lineal feet of trip, or 200 feet in distance per minute, while moving. The time lost in loading, dumping, awaiting, etc.=4 minutes per load.

A medium labourer will load with a cart in 10 hours, the following earths, measured in the bank:

Gravelly Earth, 10; *Loam*, 12; *Sandy Earth*, 14 cubic yards.

Carts are loaded as follows: *Descending Hauling*, $\frac{1}{3}$ of a cubic yard in bank; *Level Hauling*, $\frac{2}{3}$ of a cubic yard in bank; *Ascending Hauling*, $\frac{1}{2}$ of a cubic yard in bank.

Loosening, etc.—In *Loam*, a three-horse plough will loosen from 250 to 800 cubic yards per day of 10 hours.

TABLE SHOWING THE AMOUNT OF LABOUR PRODUCED BY ANIMAL POWER.

Manner of Application.	Power.	Velocity per Second.	Weight Raised, Foot per Minute.	Horses Power for the Period given.
10 Hours per Day.	Lbs.	Feet.	Lbs.	No.
Man throwing earth with a shovel a height of 5 feet	6	$1\frac{1}{5}$	480	3·7
Man wheeling a loaded barrow up an inclined plane height one-twelfth of length	132	$\frac{5}{8}$	4,950	90·0
Man raising and pitching earth in a shovel to a horizontal distance of 13 feet	6	$2\frac{1}{4}$	810	14·7
Man pushing and drawing alternately in a vertical direction	13	$2\frac{1}{2}$	1,950	35·5
Man transporting weight upon a barrow, and returning unloaded	132	1	7,920	144·0
Man walking upon a level	143	5	42,900	780·0
Horse drawing a four-wheeled carriage at a walk	154	3	27,720	504·0
Horse with load upon his back at a walk	264	$3\frac{3}{4}$	59,400	1080·0
Horse transporting a loaded waggon, and returning unloaded at a walk	1,540	2	184,800	3360·0
Horse drawing a loaded waggon at a walk	1,540	$3\frac{3}{4}$	346,500	6300·0
8 Hours per Day.				
Man ascending a slight elevation, unloaded	143	$\frac{1}{2}$	4,290	62·0
Man walking, and pushing or drawing in a horizontal direction	26	2	3,120	45·2
Man turning a crank	18	$2\frac{1}{2}$	2,700	39·0
Man upon a treadmill	140	$\frac{1}{2}$	4,200	60·9
Man rowing	26	5	7,800	113·0
Horse upon a revolving platform, at a walk	100	3	18,000	260·8
Ox upon a revolving platform, at a walk	132	2	15,840	229·5
Mule upon a revolving platform, at a walk	66	3	11,880	172·2
6 Hours per Day.				
Man transporting a weight upon his back, and returning unloaded	140	$1\frac{3}{4}$	14,700	160·5
Man transporting a weight upon his back up a slight elevation, and returning unloaded	140	$\frac{1}{5}$	1,680	19·0
Man raising a weight by the hands	44	$\frac{1}{2}$	1,320	14·4

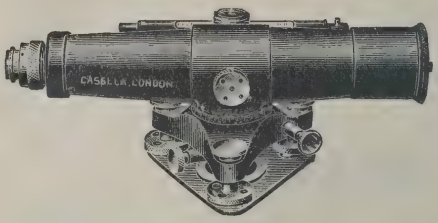
In advocating the employment of mechanical tractors on the farm, *Modern Farming* states that the horse eats annually the product of five acres. According to Edison, the efficiency of the horse is about 2 per cent.

Notes on Animal Power.

(*R. T. Hancock.*)

The amount of foot-lbs. of energy which a man engaged on heavy labour can exert during a working day is entirely bound up with fatigue and opportunity for recovery from fatigue, and is a question of physiology rather than of dynamics. The number of hours constituting a working day and the opportunities given during the working day for at least partial replacement of the waste of the muscle tissues are the governing factors. All forms of human energy, physical or mental, are similarly conditioned. All unnecessary motions or distractions produce fatigue just as much as if they formed part of the useful work done, and correspondingly reduce the useful work possible. The basis of the subject is fully treated by Taylor in his 'Principles of Scientific Management.' Instances are given of the great increase in work possible by careful attention to length of working day, provision of short periods for rest, fixing the actual percentage of the working day during which the labourer can remain under load, the optimum load, and the planning of the work to enable it to be done with the minimum of motions. The performance of labourers loading pig-iron from the ground into railroad cars an average distance of 36 ft. away was raised from 12½ to 47½ tons per man per day; of labourers shovelling iron-ore from cars, from 16 to 59 tons per day; and the number of bricks laid by a bricklayer, from 120 to 350 per hour.

The average labourer is not only incapable of planning his work so as to effect it with the least waste of energy, but many of the conditions affecting its amount are not under his control, but that of the management. The intelligence of the labourer of course plays no small part, but it is the function of scientific management, according to Taylor, to train each individual to follow the routine which the management has evolved as tending to maximum production for a given expenditure of energy. The expenditure of energy by the labourer, or the amount of fatigue involved, being much the same as where no system is followed, the increased production benefits chiefly the employer who has made this state of things possible, and the extra pay which the labourer may receive bears only a small proportion to the extra useful work he accomplishes. Even in highly skilled and specialised trades the improvement in output following on the adoption of scientific systems of work-planning is very great, but its principal field would appear to lie in the improvement of the performance of the lowest and most unintelligent class of labour. As instancing the differences which already exist due solely to the class of labour employed, Hoover ('Principles of Mining') considers that in the simplest forms of mining work, such as shovelling or tramming, one white labourer equals two to three members of the coloured races, and in the more highly skilled branches such as mechanics, the proportion rises to 1 to 7, or even 1 to 11. As under the principles laid down by Taylor the labourer eventually ceases to use any initiative of his own but becomes practically an automaton, it would appear possible to train the lowest type of labour so that they could eventually replace on an equal footing men whose higher attributes fit them for a better class of work.



SECTION III

SURVEYING.

Chaining.

Chains.—The surveying chain is 22 yards = 66 feet long. It consists of 100 links, and each link = 7·92 inches. This chain is known as 'Gunter's' chain.

Another chain is known as the '100-foot' chain, and consists of 100 links, each 1 foot long. It is used almost exclusively for work done abroad.

A third form is the 'Decimetre' chain; this is divided into 100 links, each of which measures a decimetre = ·328 foot.

Chain Measurement.—The most careful measurement that can be made with the common surveying chain is liable to an error of $\frac{1}{800}$ of the distance measured, and an ordinary measurement across fields, &c., to an error of $\frac{1}{500}$.

Chain measurement alone will not suffice for a greater extent than a square mile on a scale of 6 inches to a mile; or than $\frac{1}{16}$ square mile on a scale of 20 inches to a mile.

Arrows.—With each chain 10 arrows or pins of strong wire about $1\frac{1}{2}$ feet long, and preferably having a piece of red cloth tied to the ring of each, are carried.

Ranging.

Poles and Ranging Rods.—The former are poles of red pine about 15 feet high, 2 inches thick at the bottom and $\frac{3}{4}$ inch at the top; each should be shod with an iron shoe. The ranging rods are about 6 feet high, and have a white and red flag about 9 inches square at the top.

Offset Staff.—A narrow slip of deal about $1\frac{1}{2}$ inches wide, 1 inch thick, and 10 links long, divided into links. It is used for the purpose of measuring small distances from the line to hedges, &c.

The statute acre in England consists of 10 square chains, that is, of 10 square blocks of land whose length and breadth are 1 chain each; or, taking 10 blocks as one whole block, then an acre is equal to the area of a rectangle whose base is 10 chains and perpendicular 1 chain; or to any other rectangle, the product of whose base and perpendicular also equals 10 chains: thus, 4 chains base with $2\frac{1}{2}$ chains perpendicular, and 2 chains base with 5 chains perpendicular, are each equal to 1 acre.

With any quantity less than 1 chain, to bring feet into links add $\frac{1}{2}$ more; to bring links into feet take $\frac{1}{2}$ less.

Mensuration.

To find the Area of a Triangle when the Base and Perpendicular Height are given.—Multiply the base by half the height, or *vice versâ*.

To find the Area of a Triangle when the Three Sides are given.—Take half the sum of the sides, subtract each side severally from this sum, then multiply this and the three remainders together, and take the square root for the area.

To find the Area of a Rectangular Figure.—Multiply the length by the breadth; the product will be the area.

To find the Area of a Trapezoid.—Multiply half the sum of the two parallel sides by the distance between them.

To find the Area of a Parallelogram whose Angles are not Right Angles. Multiply the length of any one of the sides by the perpendicular let fall on it from the angle opposite that side.

To find the Area of a Trapezium.—Divide the trapezium into two triangles, and find the areas of the latter by the first rule.

To find the Area of an Irregular Polygon.—Divide the polygon into trapeziums and triangles, and find the sum of the areas of each.

To find the Area of an Irregular Figure.—Draw the figure on fine cardboard or thin sheet-metal, cut the same carefully out, and weigh it with an accurate balance. Then this weight, compared with the weight of a piece of the cardboard or metal of a definite size—say 1 inch square—gives at once the area required.

Calculation of Areas from Co-Ordinates.

If necessary adjust the traverse so that the co-ordinates correctly close the figure.

Consider each line round the figure, not the stations.

Take the total, or reduced, departures of the stations at each end of one line, add them algebraically, and divide by two. This gives the 'middle departure' of that line.

Repeat for all the lines of the figure.

It makes no difference from what initial point the departures are reckoned, whether from one of the stations on the figure, or from another point either inside or outside the figure.

Taking each line round the figure in order—it makes no difference which way round—take the difference between the reduced latitudes of the stations at each end of the line. The result is the same as the actual amount of Northing or Southing made by that particular line.

Multiply these results for each line by the middle departure of the same line, paying attention to the algebraic sign of each factor, and add all the results together algebraically.

The result is the area of the figure in squares of the units employed in measuring the length of the sides.

If these are feet, then

divide by 27,878,400 (Log 7·445 2678) for sq. miles; divide by 43,560 (Log 4·639 0878) for acres.

In the logarithmic computation of middle departures by latitudes, it is convenient to use the arithmetical complements of the logs given in preceding paragraph, adding all three logs, and thus avoiding taking out differences.

The terms latitude and departure are mutually interchangeable throughout the above.

TRIANGULATION.

For large surveys a base line is accurately measured and triangles built upon it, the sides being for 6 inches scale from $\frac{3}{4}$ to $1\frac{1}{2}$ mile. Each point should, if possible, be fixed by three distances.

Example.—AB (fig. 106) is the base line; C, D, E, F are convenient points to be fixed by triangulation.

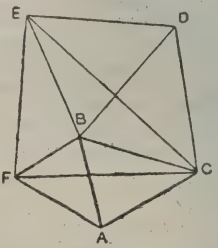

Fig. 106.

AC, AF, BF and BC being obtained, two values of FC can then be found from FBC and FAC, and then two values of FE from FEB and FEC, and so on. In plotting the triangulation the long lines EF, FC, EC should be first laid down.

AB = 5,230 feet measured by chain.
BAC = 55° 30′ 15″
CBA = 64° 21′ 25″ } measured by instrument.
BCA = 60° 8′ 20″

$$BC = \frac{AB \sin BAC}{\sin BCA}.$$

Log AB = 3·7185017
Log sin BAC = 9·9196154
13·6381171
Log sin BCA = 9·9381368
Log BC = 3·6999803
BC = 4970

The triangles are then broken up into smaller ones and measured by the chain.

Simson's Rule for Area Computation.

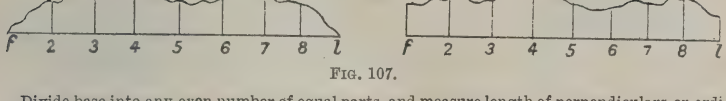

FIG. 107.

Divide base into any even number of equal parts, and measure length of perpendiculars or ordinates through each division.

If S = sum of lengths of first (f) and last (l) ordinates; E = sum of lengths of intermediate even ordinates; N = sum of lengths of intermediate odd ordinates; d = common distance between ordinates; then

$$\text{Area} = \frac{S + 4E + 2N}{3} \times d.$$

See also Weddle's Rule, p. 24.

Rate of Surveying.

The average daily progress of a good surveyor in England, surveying with one chainman, for the 6-inch-to-a-mile scale, is, according to Frome—

Close large village	about	5 acres.
Villages and surrounding fields, etc.	„	14 acres.
Close country, gentlemen's houses, etc.	„	20 acres.
Medium country, ordinary fields, and scattered farms	„	30 to 32 acres.
Open moorland, with roads, streams, boundaries, cart tracks, etc. (no fields)	„	55 acres.

A survey of a piece of country of about 6 square miles, on a scale of 6 inches to a mile (which would comprise measuring and levelling base line, triangulating, finding variation of the compass, traversing the principal roads, filling in detail by prismatic compass, contouring to every 25 feet, and completing fair plan), would take a good surveyor thirty working days.

A greater area takes less time in proportion, for the base is the same, as also variation of compass and part of the triangulation.

To ascertain the Distance of an Inaccessible Object.

To measure a Base Line across a River.

Let DA (fig. 108) be the direction of the line which has been measured up to the river. It is required to ascertain the distance BA at once upon the ground, so as to continue the measurement of the line.

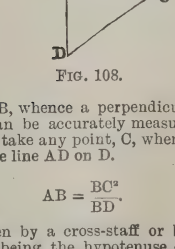

FIG. 108.

On the line DA take any point, B, whence a perpendicular, BC, can be taken, which will be free from obstruction, so that BC can be accurately measured; carry the range on across the river, and at A set up a flag; on BC take any point, C, whence A can be seen; and at C erect a perpendicular to AC, intersecting the line AD on D.

Measure DB; then

$$AB = \frac{BC^2}{BD}.$$

These angles can either be taken by a cross-staff or by the chain, with the distances of 30 links, 40 links, and 50 links; 50 being the hypotenuse of a right-angled triangle when the base and perpendicular are respectively 30 and 40.

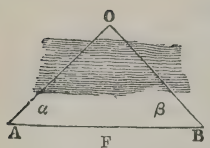

FIG. 109.

To measure the Width of a River with the Base Line alongside of it.

Take at the ends of the base line, AB (fig. 109), with a theodolite, the angles α and β, made between the base line and a flag, O, placed at the edge, on the other side of the river; then width OF is

$$OF = AB \frac{\tan \alpha \tan \beta}{\tan \alpha + \tan \beta}.$$

To find the Distance of one Object from another, where a River divides them, without using the Theodolite.

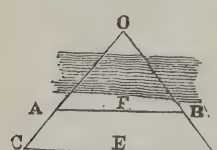

FIG. 110.

Let O and A (fig. 110) be the given objects, and AO the distance required. From A draw AB at *any* angle to AO, and produce OA to C, measuring AC about one-third length of AB; from C measure CD, parallel to AB, OBD being in one straight line. To make CD parallel to AB, at A and B erect equal perpendiculars, which can be done either by a cross-staff or by means of the unit proportion of the sides of a right-angled triangle, viz. 3, 4, and 5, or any multiples of them whatever. Then

$$AO = \frac{AB \cdot CA}{CD - AB}.$$

If the perpendicular distance OF be required, then this can be obtained by the formula—

$$OF = FE \frac{OA}{AC}.$$

Or we can so select the point A as to have OAC at right angles to the river, and make AB and CD at right angles to OAC, when AO, given by the foregoing formula, gives, of course, the required perpendicular distance.

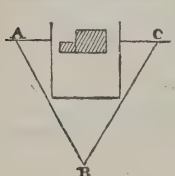

FIG. 111.

To continue the Measurement and Direction of a given Line when any Obstacle stands in the way, which cannot be crossed but can be avoided by going to the right or left.

At any point, A (fig. 111), on the given line, AC, take an angle with the given line, of 120° if you would turn to the left, or 240° if to the right, as in the present case, and proceed measuring to B till an angle of 60° made with this line towards the first line, AC, will carry you clear of the obstacle. Take this angle, ABC, 60°, and measure BC the same distance as AB; the point C will then be on the given line, and AC will be equal to AB or BC. By taking an angle of 240° with the line BC, the range of the line can be continued.

General Remarks.

1. Avoid taking bearings and distances along a circuitous boundary line like *abc* (fig. 112), but run the straight line *ac*, and at right angles to it measure offsets to the crooked line. 2. If it is desired to survey a straight line from *a* to *c*, but the instrument cannot be directed precisely towards *c*, on account of intervening obstacles, first run a trial line, *am*, as nearly in the proper direction as can be guessed. Measure *mc*, and calculate a distance, *y*, say, so that *am* is to *mc* as is 100 ft. to *y*. Lay off *ao* equal to 100 ft., and *os* equal to *y*, and run the final line *asc*. Or, if *mc* is quite small, calculate offsets like *os* for every 100 ft. along *am*. 3. When *c* is visible from *a*, but the intervening ground difficult to measure along on account of marshes, &c., extend the side *ya* to good ground at *t*; then, making the angle *ytd* equal to *yac*, run the line *tn* to that point, *d*, at which the angle *ndc* is found by trial to be equal to the angle *atd*. It will rarely be necessary to make more than one trial for this point *d*;

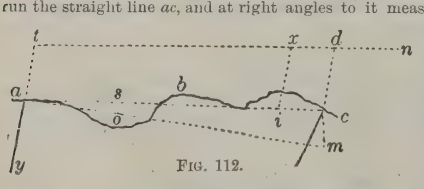

FIG. 112.

for, suppose it to be made at x, see where it strikes ac at i; measure ic, and continue from x, making $xd = ic$. 4. In the case of a very irregular piece of land, or a lake (fig. 113), surround it by straight lines. Survey these, and at right angles to them measure offsets to the crooked boundary. 5. When between two objects, m and n (fig. 114), and it is wished to place oneself in range with them, lay a straight rod, cb, on the ground, and point it to one of the objects, m; then go to the end c, and see if it points to the other object; if it does not, then, by successive trials, find the position, ed, in which the rod points to both objects, and consequently is in range with them. If no rod is at hand, two stones will answer, or two chain-pins. A plumb-line (a pebble tied to a piece of thread) will add to the accuracy of ranging the rod, or stones, &c.

FIG. 113.

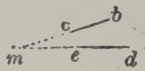

FIG. 114.

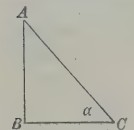

FIG. 115.

TO MEASURE THE HEIGHT OF AN OBJECT.

When the Base is Accessible.

Measure any distance from the base of the object as nearly equal as possible to the height, and take the angle of elevation by the theodolite.

Let BA (fig. 115) be the object; measure BC, and take the angle a; then

$$BA = BC \tan a.$$

When the Object is Inaccessible.

If the object be inaccessible, so that DB *cannot be measured*, range DB (fig. 116) on to C, and taking BC nearly equal to DB, measure BC, and at B and C take the angles of elevation, a and a_1; then

$$AD = BC \tan a_1 \left(\frac{\tan a}{\tan a - \tan a_1} \right).$$

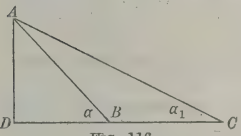

FIG. 116.

CHAINING ON SLOPES.

A = angle of slope with horizon. L = length of line chained on slope.

l = length of line reduced to the horizontal.

$$l = L \cos A.$$

5	·381	8·749	10	1·519	17·63	15	3·407	26·79	20	6·031	36·40

The foregoing table gives deductions or additions to be made every 100 ft. as actually chained along sloping ground in order to reduce the sloping measurements to horizontal ones. Even when it is so nearly level that the eye cannot detect the slope, an over-measurement of an inch or two in 100 ft. may readily occur. It is plain that if we measure all the undulations of the ground we shall get greater totals than if we measure horizontally, as is *supposed* always to be done; but since few surveyors pretend to measure horizontally until the slope becomes apparent to the eye, their lines are usually too long by from 1 to 2 inches in 100 ft. To counteract this to some extent chains are frequently made from 1 to 2 inches longer than 100 ft.; and for ordinary purposes the precaution is a good one. When greater accuracy is required the chainmen should be attended by a third person, with a rod and slope-level, for taking the inclinations of the ground. These deductions being made, the remainder will be the actual horizontal distance.

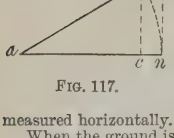

FIG. 117.

For example, in fig. 117 each 100 ft. *ao* measured up or down the slope *ae* plainly corresponds to the shorter horizontal distance, *ac*, the difference or deduction being *cn*. Taking *ao* as radius, then *ac* is the cosine, and *cn* the versed sine of the angle *ean* of the slope. Therefore *ao* multiplied by the nat. cosine of the angle *ean* gives the reduced horizontal distance, *ac*, which, taken from *ao*, gives the deduction *cn* of our table.

But if, while chaining along the slope *ae*, we wish to drive stakes that shall correspond with horizontal distances, *an*, of 100 ft., it is evident that we must add *cn* to each 100 ft. *ao*, as shown at *xe*, and the stake must be driven at *e* instead of at *o*. Observe that $xe = cn$ must be measured horizontally.

When the ground is very sloping all this calculation may be avoided, where great accuracy is most required, by actually holding the chain horizontal, as nearly as can be judged by eye, and finding, by means of a plumb-line, where its raised end would strike the ground. A whole chain at a time cannot be measured in this way, but shorter distances must be taken, as the ground requires—at times, on very steep ground, not more than 5 or 10 ft.

The following short rules may be used for finding the approximate correction to be made :—

(1.)

Square the number of degrees in the slope, multiply by $1\frac{1}{2}$, and obtain correction in hundredths of a foot.

Example.—10° slope. $10^2 \times 1\frac{1}{2} = 150$, or 1·50 ft. correction.

(2.)

Square the rise in feet per 100 ft. horizontal, and divide by 2; this gives correction in hundredths of a foot.

Example.—10 ft. rise in 100. $10^2 \div 2 = 50$, or 0·50 ft. correction.

Small-Scale Maps of Great Britain and Ireland.

Fifteen miles to one inch: British Isles.

Ten miles to one inch: Great Britain: (*a*) in outline, with water coloured blue; (*b*) hills shaded, water blue, roads sienna. Ireland: (*a*) outline engraved; (*b*) hills shaded, water blue, roads sienna.

Four miles to one inch: England: (*a*) engraved in outline; (*b*) conspicuously coloured. Also county maps with main roads coloured. Ireland and Scotland: (*a*) outline, water blue; (*b*) coloured. County maps of Scotland.

Two miles to one inch: England and Scotland; coloured.

One mile to one inch: England: (*a*) in outline with *contours*; (*b*) hills shaded in brown; (*c*) hills shaded in black; (*d*) coloured, with *contours* in red. Ireland: (*a*) in outline; latest editions with *Contours*; (*b*) hills shaded in black (unrevised); (*c*) coloured; (*d*) in outline, with *boundaries* of counties and urban and rural districts in red. Scotland: (*a*) in outline, with contours; (*b*) hills shaded in brown, zincographed; (*c*) hills shaded in black (unrevised); (*d*) coloured.

Maps of the India Survey Department.

One mile to one inch: Topographical maps; about one-eighth of the total number has been published (1914).

Four miles to one inch: Prepared in sheets of one degree by one degree. Publication only recently begun.

Thirty-two miles to one inch: The outline engraving of this new map of India and adjacent countries is completed. The hills are shown in the 'layer' system. (*a*) A new edition of the railway, canal, and road map of India. (*b*) A new map of India and adjacent countries, hills shown on the 'layer' system. (*c*) A new edition of the map showing railway stations.

DIP OF HORIZON.

d = dip of horizon, in seconds. h = height of observer's eye, in feet.

s = distance of horizon, in statute miles. n = distance of horizon, in nautical miles.

$d = 57{\cdot}4\sqrt{h}$; approximate, varying with temperature. $h = {\cdot}666s^2 = {\cdot}86n^2$.

To reduce a Measured Base to the Level of the Sea.

Let r represent the radius of the earth corresponding to the base b at the level of the sea, and $r + a$ the radius referred to the level of the measured base, B; then

$$r + a : r :: B : b, \quad \text{or,} \quad b = B \times \frac{r}{r+a}, \quad \text{and,} \quad B - b = B - B\frac{r}{r+a} = B\left(1 - \frac{r}{r+a}\right)$$

$$= B\left(\frac{a}{r+a}\right) = B\left(\frac{\frac{a}{r}}{1+\frac{a}{r}}\right) = \frac{Ba}{r}\left(\frac{1}{1+\frac{a}{r}}\right) = \frac{Ba}{r}\left(1 - \frac{a}{r} + \frac{a^2}{r^2} - \text{\&c.}\right) = B\left(\frac{a}{r} - \frac{a^2}{r^2} + \frac{a^3}{b^3} - \text{\&c.}\right).$$

But the radius of the earth being very great in comparison with the difference of level, a, we have the correction, $B - b$, or d, say, sufficiently accurate by retaining only the first term. Hence

$$d = \frac{Ba}{r} \text{ is the value to be deducted from the measured base.}$$

Spherical Excess.

$$E, \text{ in seconds} = \frac{S}{r_2 \sin 1''} = \frac{ab \sin C}{2r^2 \sin 1''}$$

S = the area of the triangle. r = the radius of the earth.

$$S = \frac{ab \sin C}{2} = \sqrt{s(s-a)(s-b)(s-c)}, \quad s \text{ being} = \frac{a+b+c}{2}.$$

Between latitudes 45° and 25° the spherical excess amounts to about 1′ for an area of 75·5 square miles.

Hence, if the area in square miles be known, a close approximation to the spherical excess will be had by dividing the area by 75·5. Log mean radius of the earth in yards = 6·8427917. If the three angles of a triangle are assumed to have been equally well determined, the previous determination of the spherical excess is not necessary for the calculation of the sides, though it will be required for estimating the relative value of the observations. For the sides of a spherical triangle may be computed as if they were rectilineal if one-third the excess of the sum of the three angles above 180° is deducted from each of the three observed angles, in which case

$$\text{side } b = \text{side } a \sin (B - \tfrac{1}{3}E) \div \sin (A - \tfrac{1}{3}E).$$

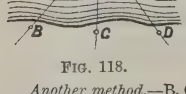

FIG. 118.

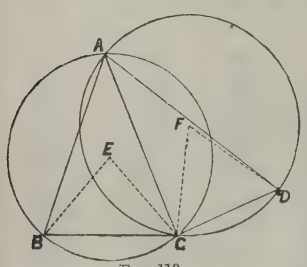
SURVEYING SOUNDINGS.

To determine the position of any sounding, A (fig. 118), when afloat, take simultaneously the bearings of three known objects on shore, B, C, D, plot the angles on tracing-paper, and move them on plan until the lines cut the points B, C, D.

Another method.—B, C, and D being known points on shore, and the angles BAC, CAD having been measured—

Double the angle BAC, and deduct this doubled angle from 180°. Halve the remainder, and set off from B and C angles, each equal to the half remainder—that is, BCE, CBE; then BE = EC. With E as a centre and radius EC, describe the circle BCA. Then the point A will be in the circumference of this circle.



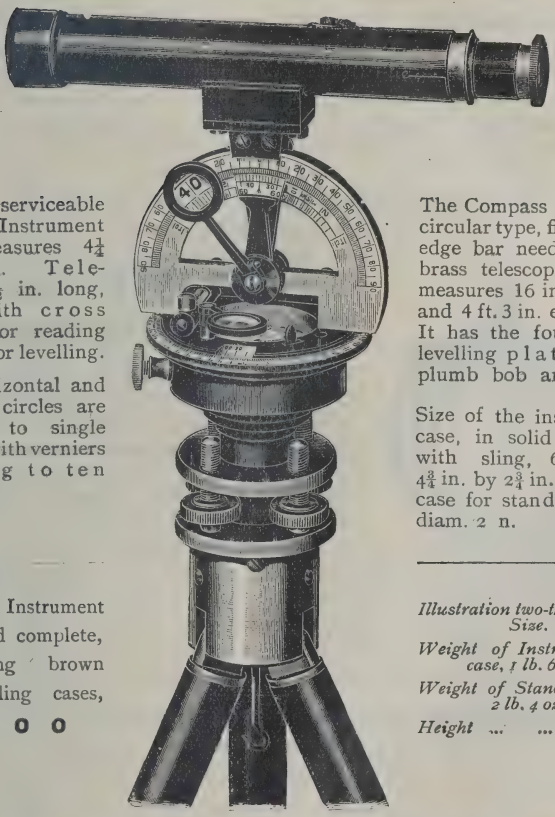


FIG. 119.

In like manner, double the angle CAD and proceed as before; the point A will be in the circumference of the circle CAD. Being in the circumference of the two circles, the point A will therefore be at the intersection of the two.

Suppose the angle BAC to have been 40°, CAD 30°, the double of BAC is 80°; then 180° − 80° = 100°, which divided by 2 gives 50°. Set off from B and C angles equal to 50°. In like manner, 2CAD = 60°, and 180° − 60° = 120°; half 120° = 60°; from C and D set off 60°. With E and F as centres (fig. 119), and radii EB, FC, describe the two circles, whose intersection determines the position, A, of the observer.

W. H. HARLING'S
Improved Pocket Theodolite.

A MOST USEFUL AND COMPACT INSTRUMENT FOR ENGINEERS, ARCHITECTS AND SURVEYORS.

This serviceable little Instrument only measures 4¼ in. high. Telescope 5½ in. long, fitted with cross webbs for reading off staff, or levelling.

The horizontal and vertical circles are divided to single degrees with verniers reading to ten minutes.

The Compass is of the circular type, fitted with edge bar needle. The brass telescopic stand measures 16 in. closed, and 4 ft. 3 in. extended. It has the four screw levelling plates, also plumb bob and hook.

Size of the instrument case, in solid leather with sling, 6 in. by 4¾ in. by 2¾ in. Size of case for stand, 16 in., diam. 2 n.

Price of Instrument and Stand complete, in strong brown leather sling cases,

£15 0 0

117 MOORGATE, LONDON, E.C. 2.

ESTABLISHED 1851.

THE 'STEWARD' POCKET SURVEYING TELEMETER with sighting telescope, will rapidly determine and mechanically compute the distance of any object within the range of vision. In Topographical Survey from a fixed point any number of minor points can be located and their distances determined from the fixed point and from each other. Distances are indicated on the scale in terms of units of the base, so that any system of measurement can be employed. Size 4½ by 1½ inches.

In Leather Sling Case - - £11 10 0

With Booklet of Instructions.

THE 'STEWARD'

Hypsometric Aneroid.

Constructed to eliminate many common sources of error. Reads to 5 feet or 2 metres without a vernier. No calculation necessary. No parallactic error. Altitude scale automatically locks. Movement compensated for temperature. Diameter of dial 3¼ inches. Aneroid fixed to leather sling case, cannot drop to ground. Swing thermometer for ascertaining air temperature.

Range of Altitude Scale	6,000 feet, reading to 5 feet	..	**£13**	**10**	**0**
Ditto ditto	10,000 feet, ditto	..	**13**	**15**	**0**
Ditto ditto	2,000 metres, reading to 2 metres		**13**	**10**	**0**
Ditto ditto	3,000 metres, ditto		**13**	**15**	**0**

These Aneroids can also be supplied with scales for higher altitudes.

THE FERGUSON SOLAR CHRONOMETER gives mean or standard time in any locality without calculation. It can be placed in the meridian by its own indications, and does not need a level surface or to be permanently fixed **£6 15 0**

J. H. STEWARD, Ltd., Opticians & Instrument Makers, 406 and 457 STRAND, LONDON.

Established 1852.

To reduce a Sounding to Low Water.

h = vertical rise of tide, in feet. h' = height of tide above low water, in feet, at the time t'.
t = time between high and low water. t' = time from time of sounding to low water, in hours.

$$\frac{h}{2}\left(1 \mp \cos\frac{180t'}{t}\right) = h' ; \; - \cos \text{ when } \frac{180t'}{t} < 90°, \text{ and } + \cos \text{ when } > 90°.$$

EXAMPLE.—Low water occurring at 3.45, and high water at 10.15 P.M., a sounding taken at 5.30 P.M. was 18·25 feet; what was the depth at low water, the vertical rise being 10 feet?

$$h = 10 \textit{ feet}; \; t = 5h.\ 30m. - 3h.\ 45m. = 1h.\ 45m. = 1{\cdot}75 \textit{ hours}.$$
$$t = 10h.\ 15m. - 3h.\ 45m. = 6h.\ 30m. = 6{\cdot}5 \textit{ hours}.$$

Then

$$\frac{10}{2}\left(1 \mp \cos\frac{180 \times 1{\cdot}75}{6{\cdot}5}\right) = 5(1 - 48°\ 27') = 5 \times (1 - {\cdot}662) = 1{\cdot}69 \textit{ feet}.$$

Sounding	18·25 *feet*.

SURVEYING INSTRUMENTS.

(W. F. Stanley.)

THE PLAIN THEODOLITE.

In this instrument (fig. 119A) there is a horizontal circle reading to minutes by two verniers, and a vertical half circle reading also to minutes by a single vernier—both readings being provided with clamps to fix the telescope nearly to the reading required, and tangent screws to make the final adjustment. Below the horizontal divided limb of this theodolite a separate axis is formed, so that every reading may be set to start from zero. The telescope has two turned collars which rest in a cradle formed of Y-form supports. This form of cradle permits the telescope to be revolved upon its axis to set it in collimation with the object glass, by adjustment of the spider webs in front of the eye-piece until the revolution of the telescope does not appear to displace any small object observed. A magnetic needle of about three inches in length is placed in a compass box over the axis of the instrument. In old instruments this is very difficult to read, from interference of vision by the standards of the telescope. In modern instruments (fig. 119A) an aluminium ring compass is provided, which is read from one side by a microscope. This theodolite is set up upon a tripod stand and adjusted to level, before commencing a survey, by four adjusting screws (parallel plate screws) which are used oppositely to tip the instrument one way or the other until the bubbles of the level tubes on the limb are brought to the centre of their run. As the pressure of these parallel plate screws must be more or less according to the force used, the axis is slightly distorted by them; dull bubble tubes have therefore to be used. Where greater exactness is required, the support, as of every scientific instrument, is placed upon three points only, an arrangement which is termed the tribrach system, and which admits of quick adjustment.

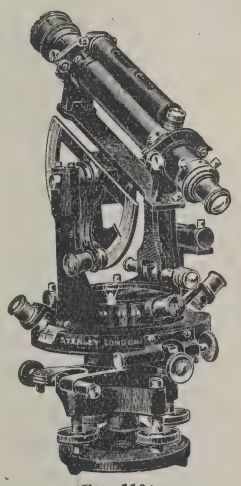

FIG. 119A.

To set up a Tribrach.—Place the level linable with either pair of screws B.C. (fig. 119B, p. 150), and bring the bubble to the centre of its run. Then place the level at right angles to this, so that the screw A comes opposite the centre of the telescope. Bring the bubble to the centre of its run. Now return to first position to see that this is right. If not exact, repeat the operation.

With tribrach support a modern well-ground bubble will read sensibly to five seconds of arc, or, if required in high-class work, even to a single second or less.

ADJUSTMENT OF THE THEODOLITE.

(R. T. Hancock.)

The first and most important adjustment consists in correctly levelling the instrument with its vertical axis pointing truly to the zenith, every time it is set up. Other errors in adjustment can be corrected or compensated by special methods of observation, but correct results are impossible if the theodolite is out of level. This adjustment must precede all others.

Set the instrument up firmly with its legs well spread and bring it approximately level by means of the base adjusting screws, with the aid of the bubble tubes on the vernier plate. Place the telescope as nearly horizontal as possible, with the vertical arc clamped to zero if desired, and bring it over one pair of the base levelling screws, or parallel to a pair in the case of a tribrach base, and observe the position of one end of the bubble of the telescope level in relation to the gradations on the tube. Select and use one end throughout, say, the end of the bubble nearest the eyepiece. Revolve the upper part of the theodolite through 180°, bring the bubble back half way, if it has moved, by means of the base levelling screws. Check by turning the instrument back to its original position. If the bubble remains in its mean position, turn the upper part of the instrument through 90°, so that telescope lies over the other pair of levelling screws, or the remaining one of the tribrach, and bring the bubble to the same position by these. Finally check by turning the instrument slowly through 360°, and see that the bubble remains unmoved. If not, repeat adjustment from the beginning. The bubble may not finally occupy the centre of its tube : this is unimportant. What is important is that it should not move when the instrument is revolved about its vertical axis. If the bubbles of the levels on the vernier plate are not well centered when the instrument is thus levelled, it will be convenient to make them so now by means of the turret screws at the ends of the cases, so that a close approximation to true levels may be obtained when setting up on future occasions. It should make no difference in levelling up whether the two plates revolve together or whether the lower is clamped and the upper free. If it does, it shows that the cones require regrinding.

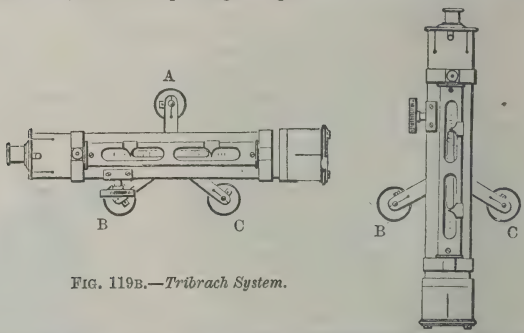

FIG. 119B.—*Tribrach System.*

Adjustment for parallax consists in moving the eyepiece in or out, altering the focus of the object glass to correspond, until the crosshairs of the diaphragm do not appear to move relative to the point viewed when the eye is moved slightly from side to side of the lens opening. Care should be taken not to revolve the eyepiece tube in its casing, as this affects the optical centering of the system of lenses. For this reason the lens cell and its casing are usually provided with corresponding marks by the maker.

The transit axis upon which the telescope swings should be accurately at right angles with the vertical axis of the instrument. The adjustment of this is effected by sliding bearings at the top of the standards, but in cheaper instruments no provision for adjustment in this respect is made, the makers supposedly securing it once and for all by correctly proportioning the height of the standards. Direct the telescope to some high object, such as the finial of a spire. Depress the telescope and mark on the ground the point where the intersection of the hairs falls. Transit the telescope, sight up again, and mark where the intersection falls on the ground the second time. Raise or lower one bearing so that the intersection falls one-quarter of the distance between the marks from the second mark. Check, and repeat if necessary.

The collimation line may be defined as a line joining the optical centre of the object glass and the intersection of the crosshairs. To make it at right angles to the axis on which the telescope swings, set up, level, and sight to a well-defined mark about 100 feet away ; transit the telescope, and mark where the intersection falls in the opposite direction, at about the same distance away and on the same level as near as may be. Revolve the plates through 180° about, and sight to the original mark. Again transit, and mark the new point of intersection, if altered, near the former one. Measure a point one-fourth of the distance between the two from the latter, and move the diaphragm carrying the crosshairs by means of the adjusting screws holding it in the telescope until the intersection covers the measured mark. It will be necessary to loosen all four screws to do this, but care should be taken not to move the diaphragm up or down more than can be helped, and to keep the crosshairs vertical and horizontal. Check by transiting back again to the original mark, which will now not fall under the crosshairs ; bring it under the intersection by the slow motion tangent screw, and transit back again. The intersection should now fall half way between the two original marks.

Having performed the foregoing adjustments we now have the vertical axis of the instrument pointing truly to the zenith, the horizontal axis on which the telescope swings truly at right angles

to the vertical axis, and the line of collimation truly at right angles to the horizontal axis. The collimation line then lies wholly in a vertical plane cutting the horizontal axis at right angles, but does not necessarily lie parallel to the axis of the level on the telescope in that plane. It can be made to do so by altering the lie of one or the other, and in order to avoid disturbing the adjustment just completed, it is better to bring the axis of the telescope-level parallel to the collimation line as it now lies. This is why it was recommended not to disturb the up-and-down position of the collimation line more than can be helped, so as to avoid the necessity for much alteration in the telescope level. This adjustment is not really required for the theodolite, unless it is intended to use it occasionally as a level, and the surveyor who desires to effect it can proceed as described below for the level, except that after setting up beyond the levelled pegs, the telescope is lowered or raised by the slow-motion tangent screw of the vertical arc till the crosshairs read the same on both pegs; the bubble of the telescope level is then brought to the centre of its run by altering the capstan-headed screws at each end of its casing.

Everest's Theodolite.

This instrument was much used in the survey of India, and is a modification of the plain theodolite, in which the cradle fitting, somewhat liable to derangement from its light loose parts, is replaced by a telescope fixed in a solid collar. The segments of arc of this theodolite are used upon each side of the axis, so that double vernier reading may be employed to vertical angles. It was the first English-made theodolite in which the tribrach system of adjustment was employed, and is still considered to be an excellent instrument for survey upon fairly level country.

Lister's Inclinometer.

The construction (fig. 119c) is similar to that of a plain theodolite, but with the addition of an extra vertical axis to the telescope, carried through the horizontal axis at right angles. By this means the telescope can be moved upon this supplementary vertical axis in a plane of any inclination desired, so that if the horizontal axis is set to the slope of a railway cutting a large number of pegs may be set out continuously with the same setting by direct observation through

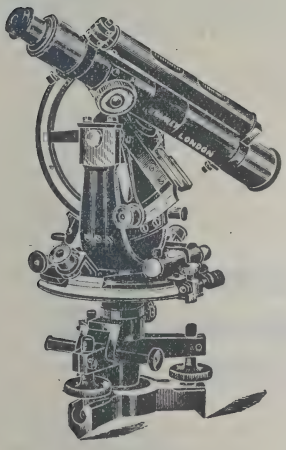

Fig. 119c.

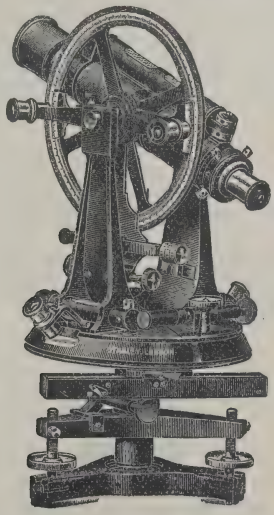

Fig. 119d.

the telescope across any irregularity or inclination of the land surface. The slopes for curves also are readily pegged by means of the special horizontal angle repeater with which the instrument is fitted, so that one angle only need be set and that can be repeated round a curve until complete, when the angle repeater is simply released to return to a straight line.

The instrument is readily made into an ordinary surveying theodolite by fixing the telescope by means of a catch, which places it firmly true to the reading of the arc and limb.

Transit Theodolite.

In modern practice this instrument (fig. 119D), in some form, is generally used. Its great merit is that the telescope being placed high enough above the limb to revolve over half a revolution on its axis, a direct fore-and-back sight can be taken in line with its centre, and, as this may also be done by moving the reading through 180°, it is a good test for the division and the true centering of the instrument. Except for the transitting telescope the general principle of structure of this theodolite is the same as that of the plain theodolite above described. The height necessary for the telescope is generally somewhat reduced by replacing the circular magnetic compass by a magnetic needle placed in a trough under the limb. The needle can move only 20° of arc, but, as it can be brought co-incident with the magnetic north by the lower adjustment of the axis of the theodolite, this arc is quite sufficient. It possesses the advantage of having a longer needle placed in clear daylight for observation. With the bad object-glasses formerly used the cradle adjustment in Y's was necessary for true collimation. In modern instruments the object glasses are truly centered so that the webs or other indices may be placed exactly in the axis of the telescope. On this point, in the old pieced-up instruments every severe shake or journey threw the instrument out of adjustment, and it was necessary that the experienced surveyor should have every facility for restoring this. In modern good work with refined apparatus for adjustment, a permanent index, or diaphragm, as it is termed, may be fixed to position by the maker, which will remain in perfect adjustment with careful usage the whole life of the surveyor. As this index matter is a subject not too well known, it will be discussed further on.

Notes on Diaphragms.

Spider's Webs (fig. 119E)—the oldest form of telescope index—are clear and good, but very delicate, sagging with damp and breaking by tension if they remain so long in the instrument as to become very dry. Unless the user is specially skilled, the re-webbing and re-adjustment must be done by an optician.

Lines on Glass (fig. 119F).—These are accurate and permanent. The presence of the glass diaphragm obstructs a little light at all times, but the great defect of this diaphragm is that it becomes bedewed by changes of temperature and requires cleaning. Where glass is fitted it should be easily removable with means of returning it exactly to its former adjustment.

Point Diaphragms (fig. 119G) should be formed of very sharp fine needle points made of platinum-iridium alloy, which is as hard as finely-tempered steel and is non-corrosive.

This index gives the most exact reading and is permanent, so that an instrument with points will remain in adjustment for many years. In case of dust on the points this can be removed gently with a camel hair brush. The only objection made to this diaphragm is that it requires great care in bringing an object exact to reading, but certainly not greater care than is always desirable. Its precision may be demonstrated most simply. Upon first impression the

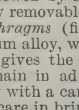

Fig. 119E.

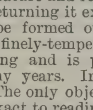

Fig. 119F.

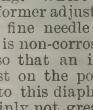

Fig. 119G.

point may not appear so fine as a web. Practically it is more exact, as it does not cover the reading, as will be seen by the magnified appearance of the readings (fig. 119H).

Both these readings are of ·4 upwards of the black band, but this quantity is less clear with the web W W than with the point P. This principle is most important with subtense measuring as will be shown presently.

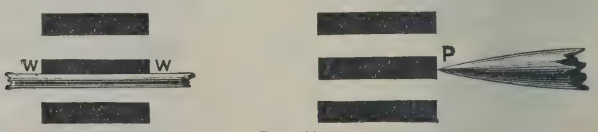

Fig. 119H.

Some objections have been made by railway engineers to the large size of the transit theodolite, as they do not require the vertical circle except occasionally in mountainous districts. To meet this difficulty Messrs. W. F. Stanley & Co. Ltd. have made a transit theodolite (fig. 119I) as low and as portable as the plain theodolite. This transits over the eye end only, which is loaded by a heavy casting to balance the object end, which is made in aluminium for lightness.

Tunnelling Transit Theodolite.

This is a most useful form (fig. 119K) for all underground work. It is built very low and the telescope transits. The vertical axis is made hollow, so that any angle to about 10° may be read

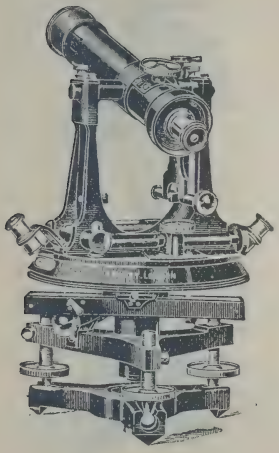

FIG. 119I.

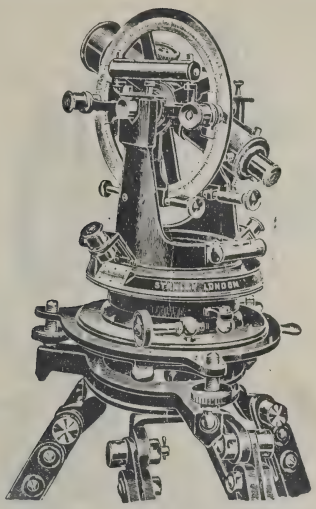

FIG. 119K.

directly below the vertical. This will be found very useful in transferring lines underground from the surface, by sighting down a shaft, and also for plumbing. The hollow centre is supported upon a sliding fitting so that it may be displaced 1½ in. about the centre of the tripod and clamped to its position. It is a form of theodolite most convenient for the mining engineer, in which a long diagonal eye-piece permits a surface line to be observed from the bottom of a deep shaft.

DUNBAR SCOTT'S AUXILIARY TOP AND SIDE TELESCOPE.

Is fitted to theodolites for reading steeper horizontal angles than can be read with the ordinary telescope, also precipitous vertical angles. The zenith-nadir telescope is placed on top of telescope for the former and upon the outside of the standards to project beyond the limb for the latter. This telescope can also be removed so that the instrument then becomes an ordinary transit theodolite.

MICROMETRIC THEODOLITES.

In modern practice for superior triangulation, a vernier reading does not give the necessary accuracy, so the more exact system of reading by a microscope provided with a fine scale in the focus of the eye-piece is employed; over this scale an adjustable web is moved by a fine screw with divided head. With this appliance (fig. 119L, page 154) much finer divisions may be made upon the instrument, and the micrometer scale will subdivide these divisions to read to any exactness desired. Micrometers were formerly employed upon large theodolites only. In modern practice they are used for as small as five-inch circles. The precision of the micrometric system may be shown in that a vernier on a six-inch theodolite can only be made to read satisfactorily 20 seconds of arc. The micrometer on the same instrument will read clearly five seconds. As a rule six-inch instruments are made to read to five seconds; five-inch, to ten seconds; eight-inch, to two seconds; ten-inch, to single seconds. It is necessary with micrometric instruments, even five-inch, that they should be figured at every degree; large instruments to half degrees. The micrometric theodolite is made the same in general structure as the ordinary transit, except for the micrometer.

THE OMNIMETER.

The omnimeter (fig. 120, page 154) is an instrument in which the tangent to a radius reads direct from the axis of the telescope to a rule or stadia of constant length, so that the subtense angle varies with the distance. The instrument consists of a theodolite to which the subtense tangential system is added. In the construction of the instrument there are two sights, one, a telescope to sight the object, and the other, a powerful compound microscope to read divisions upon a tangential scale. The telescope and microscope are united together at 90° to each other with their axes exactly crossing the transverse axis of the theodolite, so as to move together through the

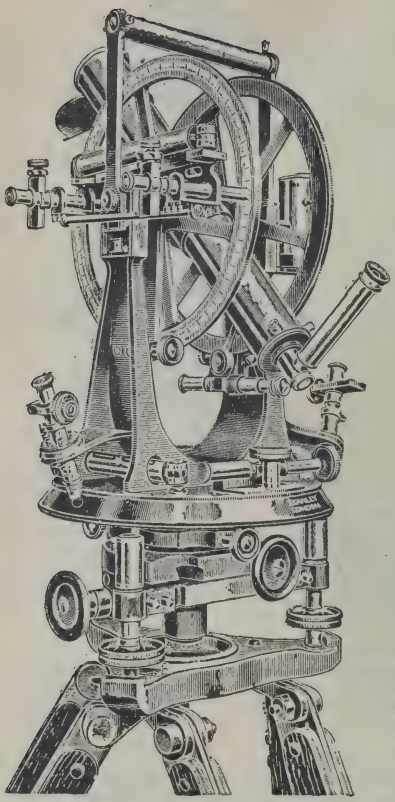

FIG. 119L.

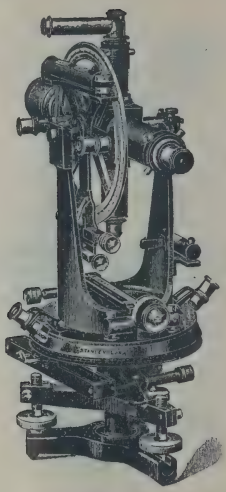

FIG. 120

same amount of angle by the motion of the telescope in traversing the azimuth. A delicate level is placed upon the telescope, and when the bubble is in the centre of its run the scale is at right angles to the axis of the microscope. The scale, which lies flat on the limb at a central distance of six inches, is four inches long, placed in a sliding fitting to adjust longitudinally to its central position by means of a micrometer screw. It is generally divided into 100 parts for numerical calculation. The divisions are subdivided by shorter lines, making the total division 200. The micrometer screw has fifty threads to the inch, and moves over one of the divisions of the scale only. The micrometer head is divided into 100, numbered at the tens ; a vernier placed against the head subdivides each of these divisions into five, making the total micrometer 500 for one complete revolution. The total division of the four-inch scale therefore becomes : 200 (divisions of scale) × 500 (micrometer) = 100,000 in four inches. The scale is placed centrally to the instrument, so that when the telescope is level the microscope is vertical, and reads 50,000 when in perfect adjustment.

The mathematical theory of the instrument is very simple :

In fig. 121, O is the centre point of the axis of rotation, directly over the divided scale, AB ; O*b*, the base line of the instrument, which may be found by experiment or by calculation ; *mn*, a staff of known length, say 10 feet ; *b*, the departure-point of the scale when the telescope is parallel to AB ; in this position, from the nature of the construction, the microscope points in the direction of the line O*b*, which is perpendicular to AB.

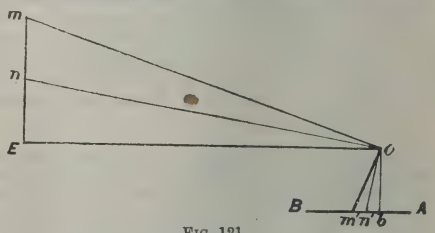

FIG. 121.

Then if the telescope be pointed to *m*, the microscope will be directed to *m'*, the line O*m'* being

perpendicular to the line Om. Again, if the telescope be directed to the point n, the microscope will be in the direction of On' and perpendicular to On. Omn and $Om'n'$ being similar triangles, we have $m'n' : Ob :: mn : OE$; the perpendicular distance from the line mnE passing through the staff mn, $\therefore OE = \frac{mn \times Ob}{m'n'}$; $m'n' : bn' :: mn : n$E, consequently the altitude nE $= \frac{mn \times bn'}{m'n'}$, or $= \frac{bn' \times OE}{Ob}$.

The perpendicular Ob, which is termed the base line of the instrument, when the temperature is not very variable, may be found very accurately by taking OE about 100 feet, and placing the 10-foot staff, mn, as shown in fig. 121; for we have $Ob = \frac{m'n' \times OE}{mn}$.

Let $m'n'$ be $= 47{,}735 - 46{,}015 = 1{,}720$, as in the example we have taken; and suppose the staff $mn = 10$ feet between the upper and lower marks, $Ob = 6$ inches (by construction), therefore $Ob = 150{,}000$ equal parts, when 4 inches contain 100,000 such parts.

$$\therefore OE = \frac{mn \times Ob}{m'n'} = \frac{10 \times 150{,}000}{1{,}720} = 872{\cdot}09 \text{ feet.}$$

Hence, for calculating distances we have the following easy rule: Multiply the length of the staff in feet by the length of the base of the instrument in micrometric equal parts, and divide the product by the difference of the two micrometer readings (of the staff); the quotient will be the required distance.

Subtense Measurements. Tacheometers.

It is quite common at present to place a pair of webs—or much better, a pair of points—in the diaphragm of a theodolite or level, these being at such a distance from each other that they will by vision correspond to a measurement (upon a distant levelling staff), which is proportional to the base of the subtense angle, so as to show thereby, in the space between the lines or points, the true distance of the instrument from the staff. Fig. 121A shows the form these points appear in focus of the eye piece. By the employment of this system chain measurements are entirely dispensed with, and the system has the merit of a simple sight measurement, as upon a rule, without any calculation. Theoretically it is scarcely as exact as the work of the Omnimeter, as there is great difficulty of exact adjustment of the points without the use of complicated optical means, but practically, as testified in some recent work by the Surveyor-General of Lagos and Nigeria, a good instrument in correct adjustment may be read within less than ·001

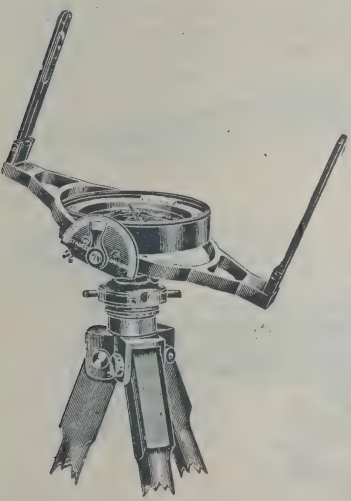

FIG. 121A.

FIG. 121B.

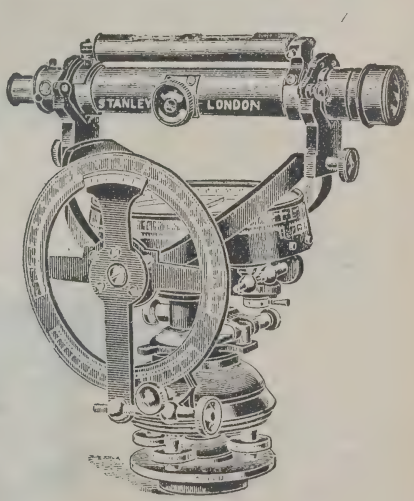

FIG. 121C.

of total distance, which is nearer than is possible by chaining over uneven ground. One merit over the Omnimeter is that the instrument is not touched by the hand during the observation of the points, cut by vision upon the staff, which give the distance.

Mining Surveying Instruments.

Where the mining theodolite cannot be conveniently used, in consequence of the absence of height of gallery, constant short turns or otherwise, as also for economy, some form of mining dial is used. One of the most general is Hedley's (fig. 121B, page 155). This being sighted only, it permits the eye to take observation from nearly the top of a gallery or cutting. The sights rock on an axis to any desired inclination, which may be read off on a small divided arc on the side. The compass reads by an edge bar needle. Dials of various patterns are made into instruments nearly resembling theodolites, the important points being observed that the instrument must be low and light, and read as nearly as possible at its highest part. The tripod of a dial is made with the legs to separate about the centre so that the instrument may be brought low, or what is better with sliding legs to adjust to any height required.

Stanley's Cranked Gimbal Dial.

This instrument (fig. 121C, page 155) is fitted with sliding stand with solid head, and an improved form of ball head to give the necessary amount of tip to the instrument, when the tripod is upon sloping ground, to bring it level. It has clamp and tangent movement to the lower axis, also to the limb, which is outside reading by two verniers to single minutes. The gimbal is cranked so that the telescope will read 90° both ways, thus enabling a bearing to be taken of any object upon the surface from the top of the shaft, and a line being sighted at the bottom of the shaft in the same vertical plane with it, without changing the horizontal adjustment of the instrument. It is also useful for taking vertical sights up a shaft. The vertical arc has a clamp and tangent, and is divided to read single minutes. The telescope is fitted with stadia points for reading distances *without the use of a chain*. It is also fitted with folding sights for use without the telescope and a needle pin to lock compass at zero. The entire instrument is constructed as low as possible for use in shallow workings.

The Dumpy Level.

This is a perfect knock-about instrument. If stations are taken at equal distances apart, say one chain, this form of level will act correctly although out of adjustment. Thus with the level

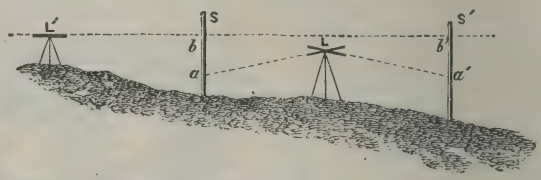

Fig. 121D.

at L (fig. 121D). place a staff vertically at one chain distance from the instrument at S. The inaccurate instrument will read the staff at A. Now place the staff vertically at S'. It will read at A'. The distances and verticality being equal, A and A' will be level. If we now place

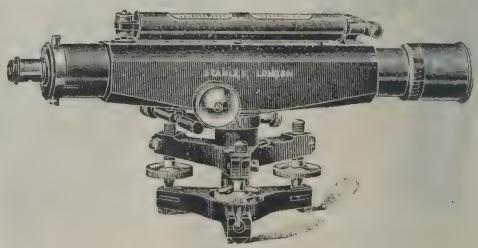

Fig. 121E.

the level at some distant position nearly in line L′ and adjust the level by the bubble screw to read equal distances above *a* and *a′* as *b* and *b′*, the level must be true.

The stability of the level, without increase of weight, has always been a very desirable consideration with all engineers. This is best attained by shaping the level as nearly as possible out of solid castings. Fig. 121F (page 156) shows a level made in this way, and it is the strongest and most compact level made.

Adjustment of the Level.

(*R. T. Hancock.*)

Select a fairly level piece of ground, set up the instrument, carefully levelled up as described or the theodolite (p. 149), and drive a peg at a distance of 100 feet or so away. Hold the levelling staff on the peg and note the exact reading. On the opposite side of the instrument, and exactly the same distance away, set another peg, driving it down till the staff held on it reads exactly the same as on the first peg. The tops of the pegs are then on the same level, independent of instrument error. Set up on the prolongation of the line beyond one of the pegs, level up carefully, and make the crosshairs read the same on both pegs by raising or lowering the diaphragm cell by means of the screws holding it in the telescope tube. The collimation line is now horizontal.

It is not necessary to level the pegs if the difference in level is noted, and the crosshairs are altered to read the same difference. To facilitate the adjustment in this case, set up beyond the pegs at a distance which bears some simple relation to the distance between the pegs, make a sketch of the position of instrument and staffs, insert readings and distances, and calculate the amount it is necessary to alter the reading on either staff (by moving the crosshairs), on the principle of similar triangles.

The telescope bubble may not finally occupy the centre of its tube when the collimation has been put horizontal as described. This is unimportant, as the instrument can always be correctly levelled up if the procedure as described for the theodolite is followed, in fact the central position of the bubble should never be relied on as a test for levelling up, even if it has once been secured by adjustment. It may be brought to the centre of its run by adjusting the screws holding the level to the telescope, care being necessary not to disturb the instrument.

The Gradiometer.

This instrument (fig. 121F) (*Stanley's patent*) is designed for taking vertical inclines at fixed small angles for railways, irrigation, drainage works, &c., &c., by means of an open extended scale, which may be conveniently and distinctly read without the use of a vernier.

It is also the most rapid levelling instrument yet made, as the telescope can be put level instantly at any sight by moving the drum, without any setting up whatever by the levelling screws. When the drum is at zero it forms an ordinary level of the most approved form. The gradiometric arrangement is effected by the telescope being mounted in trunnions, one being adjustable vertically: the amount of elevation or depression being indicated by a drum graduated to read rise or fall from 1 in 12 to 1 in 1,200.

The additional parts do not increase the size, and add little to the weight.

By its use a great saving of work is effected; for instance, a town drainage in which it is desired to work out an inclination which the levels indicate to have a fall of, say, 10 feet between the extreme points. If the line which the drainage is intended to take is measured, then however angular or zigzag it may be, the length of that line will be that into which the 10 feet is to be divided: thus if the line of streets measure 5,000 feet, this gives 1 foot in 500. Therefore if the drum is set to that proportion, then all the pipes may be laid directly without further setting.

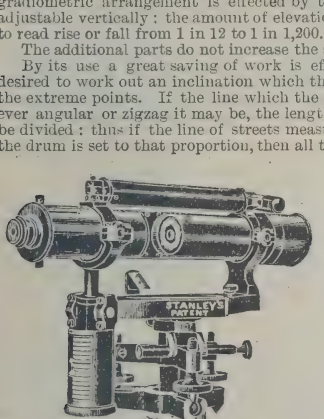

Fig. 121F.

For levelling on steep inclines the instrument also saves a great number of settings up, as instead of levelling for say every 14 feet rise or fall, the gradient of the total distance can be taken, and also the distance, by stadia reading, and by reference to a gradient table the difference of level can at once be seen. Telemetrical readings at great distance may also be taken with accuracy by this instrument.

This gradiometer has been adopted by the Government for producing contour maps.

Box Sextant.

This is the most convenient instrument for filling in details of work performed by the theodolite, or for small surveys. It is constructed upon the principle of the nautical sextant, but the arrangement is made very portable by being placed in a circular box. The radius arm reads to single minutes. It is provided with dark glasses for adjustment upon the sun.

The adjustment is best performed by setting the sextant so that the sun appears a perfectly cir-

cular disc in the telescope with the index at zero. In defect of the sun some distant object may be taken, such as one edge of a chimney, house, or flagstaff, this object being looked at through the eye-hole and horizon glass. Turn the index arm, by means of the large mill-headed screw, until the reflected image of the selected object coincides in the horizon glass with the object seen direct. Having effected this, the vernier should then be examined, to note whether the zero-point of the vernier coincides with the zero-point of the arc. If this coincidence occurs, and the observed object be distant *fully half a mile*, then the instrument is in horizontal adjustment, but if the two zero-points do not agree, the index arm is moved until they do, and the key placed in the key-holes by the side of the sextant to move the horizon glass by which the reflected image of the distant object is made to coincide with the object seen direct through the lower part of the horizon glass. The key is inserted in the keyhole on the *top* of the instrument when it is required to move the image up or down for vertical adjustment. In all cases it is better to see that a perfect disc of the sun appears in the telescope when the index is at zero.

The Plane Table.

This instrument is now generally used in new countries and in our colonies, for filling in details of work with the theodolite. It has the great merit that an intelligent native without technical education can be instructed to do valuable detail work with it. In its simplest form

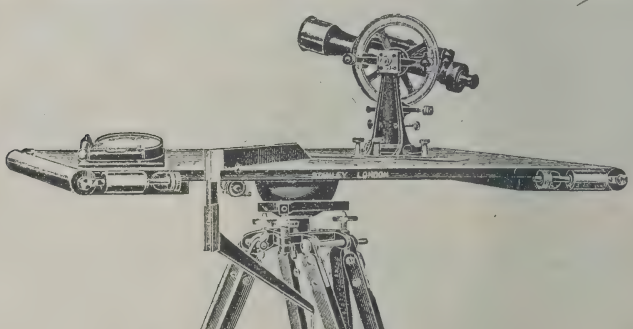

Fig. 122.

it consists of a sighted rule placed on a small board supported by a light tripod, the work being performed on the surface of paper. Many civil engineers find its work extremely convenient, because this work being made most definite by sketches upon the paper used, from these sketches they have a certainty of position in making maps from the same; so that they employ plane tables with all the refinement of means of observation possessed by the theodolite. One of these instruments is shown by fig. 122.

Prismatic Compass.

Details of small surveys or filling-in work are made by this compass, which is sighted for observation of direction, so that the eye may also see the compass ring by reflection through a prism at the instant of sighting. A reflector is commonly fixed to the forward sight so that distant objects may be seen up or down hill. The instrument is generally held in the hand for work, but where greater refinement is desired it is supported on a tripod stand. 2½ in. or 3 in. instruments are used by hand; 3½ in., 4 in., and 4½ in. are each set on a stand.

The Abney Reflecting Level.

A small level to hold in the hand. For flying work and approximate measurements from bench marks on an ordnance map the instrument is very useful. It may be used to level uphill from or to a bench mark by setting to zero and taking successive horizontal sights to points on the ground such as a stone or a daisy. The observer walks to the daisy and takes another forward sight, and so on up to the point whose level is required. Then the difference of level is the height of the observer's eye × number of sights taken. Or if the site is visible from the bench mark it can be sighted at once, the bubble being brought to the line of sight and the angle of the vernier arm read. The distance horizontally can be measured on the map, and the difference of elevation is this length multiplied by the tangent of the angle.

(See also 'Surveying and Levelling Instruments,' Stanley: published by E. and F. N. Spon.)

The Steward Surveying Telemeter.

(J. H. Steward, Ltd.)

This Pocket Telemeter (fig. 122A) is especially useful when the survey of a tract of country, a preliminary survey for a railway, or some topographical reconnaissance, has to be made in a short space of time, and when the transport of cumbersome instruments is inconvenient. The size of the telemeter is $4\frac{1}{2} \times 1\frac{1}{4}$ in., and its weight 10 oz.

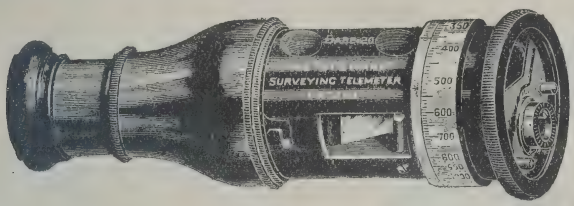

FIG. 122A.

The arrangement consists of two plane mirrors mounted upon pivots and serving as index and horizon mirrors. The mirrors are mounted upon a base enclosed in a metal tube, to one end of which is attached a small sighting telescope. To the other end is adapted a movable collar, connected to the index mirror by means of a metal arm. By rotating this collar the index mirror is moved in azimuth, and the angular displacement is measured by reference to a graduated scale upon the exterior of the collar. When the scale is set to zero the mirrors form an optical square and reflect a right angle. A small toothed wheel attached to a screw acts on the horizon mirror so that the angle of double reflection can be varied about 5 degrees out of the right angle, in order to facilitate the determination of the direction of the base.

The scale of distances is divided upon the German silver rotating collar, each division representing 10 units of distance. Any unit of measurement may be employed with the Telemeter, the graduations showing the range in terms of units of the base.

The principle of the Telemeter is to measure the two angles at the extremities of the base, forming a triangle with the object of which the distance is required. The distance or range of the object is read directly from a scale graduated on the instrument, and is expressed in terms of units of the base, so that any scale of measurement (yards, feet, metres, etc.) may be employed. The scale of distances is computed for a base of 20 units, and as the unit of measurement employed may be of any length, it follows that distances of any length can be determined, the limit of distance being governed by the length of base that can be employed and the visibility of the object. The instrument is also adapted for use with a base which is of constant ratio to the distance of the object.

The accuracy of the indications is assured by empirically graduating the scale. The results obtained with the Telemeter have been most satisfactory, the mean error working out at less than 1 per cent.

The Steward Hypsometric Aneroid, with Swing Thermometer.

(J. H. Steward, Ltd.)

This aneroid (fig. 122B) is constructed so as to eliminate the many sources of error present in aneroids of ordinary construction and to facilitate operations by doing away with the necessity of calculations.

The altitude scale is regularly divided, to the left for 'ascents' and to the right for 'descents,' and forms a complete circle of equal divisions closed at the two extremities. The zero of the altitude scale can be displaced relatively to the barometric scale and set opposite the index hand at any point of the barometric scale without introducing an error; consequently it is only necessary to set the zero to the index hand by means of the rack and pinion at one station, and the index hand will indicate the difference in altitude at the next station. The divisions are so arranged that with an altitude scale extending up to 10,000 feet, differences as small as five

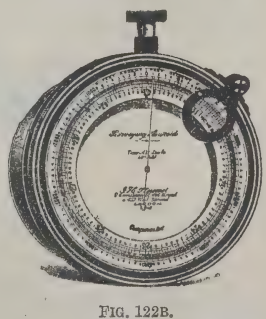

FIG. 122B.
The Steward Hypsometric Aneroid.

feet or less can be read without the application of a vernier ; and by a special arrangement of the reading lens there is no error of parallax. The movement being compensated, changes of temperature do not affect the readings. The aneroid is read and set without removing it from its case, and the altitude scale is automatically locked so that it cannot shift during transit. The diameter of the dial is 3¼ in. A small swing thermometer, for ascertaining the air temperature, to make the correction for difference in the weight and volume of the atmosphere, is carried in a pocket at the back of the case.

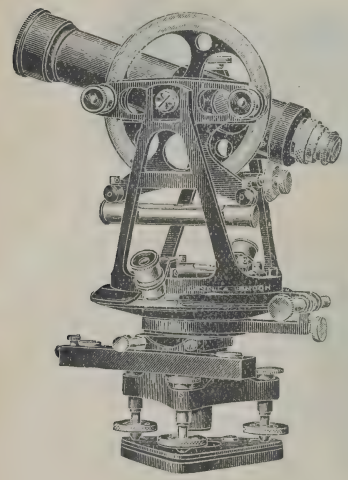

FIG. 122C.

THE CASELLA THEODOLITE.

C. F. Casella & Co. Ltd.)

In recent years, the tendency of many British makers of surveying instruments has been to design lighter and more compact models than those previously in use. Strength has not been sacrificed to lightness in weight, nor convenience to a compact design, for these newer models are often both stronger and more convenient.

The theodolite shown by fig. 122C has several special features. It has internal focusing for the telescope, an improved trough compass (watertight and easily taken to pieces), a screw-focusing eyepiece, and a simple but effective centering head. The clamps operate on the axes of circles, and not on the peripheries, and are therefore less liable to strain the instrument. The horizontal circle is 5 in. in diameter and the vernier gives readings to 20 or 30 seconds. The vertical circle is 4 in. in diameter, with readings to 30 or 60 seconds. The instrument packs into a case measuring only 14 × 8 × 7 in., and the weight of the instrument and its case is only 16 lb.

THE CASELLA DUMPY LEVEL

(*C. F. Casella & Co. Ltd.*)

The Dumpy Level, fig 122D, is very much smaller in build than the pre-war pattern, although the telescope itself is larger and has specially good optical properties. The centre of gravity

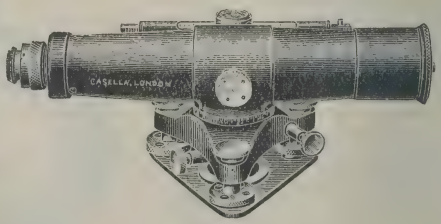

FIG. 122D.

of the instrument is low, and the danger of a fall injuring it is very much reduced. It is sometimes fitted with a divided horizontal ring, reading to 1° or 0·5°, which is used for contour work or for setting out angles of buildings, etc.

The tripod stands of both these instruments are light though rigid.

TO FIND THE VARIATION OF THE COMPASS.

1. By the Pole Star (Polaris).

The pole star is on the meridian, either above or below the pole, when a vertical plane passes through it, and the bright star at the root of the tail of the Great Bear ϵ Ursæ Majoris (Alioth). Thus, during the twenty-four hours, two opportunities will be presented of finding the pole star on the meridian. Set up a fine plumb-line in a convenient place, free from currents of air, and the observer, placing himself behind the thread, waits until the moment when the two stars are hidden by the thread. If the bearing of the pole star be then read, it will show the variation of the compass. But as it is not very easy to read a compass at night, it is best to fix a stick with a light on it in the line of the pole star, and as far off as possible, the line joining the observer's position, and the light is the meridian line, and its bearing may be read in the morning.

2. By a Single Altitude of the Sun.

1. Compare watch with chronometer to get correct mean time.

2. Note readings of barometer and thermometer.

3. Adjust theodolite and note index error.

4. Set up instrument at . . . . . Δ station; make the temporary adjustments, and set instrument at 360° on . . . . . Δ station.

5. About three hours from 12 o'clock, morning or afternoon, unclamp upper horizontal plate and vertical arc. See that the dark eye-piece is down, and move upper part of instrument till the sun is in the field of object glass. Clamp upper horizontal plate and vertical arc, and with the two tangent screws follow (morning observation) the sun's movement till the sun's upper limb just touches the intersection of the cross-hairs. Note the time by watch, and read on horizontal arc the azimuth, and on vertical arc the altitude of $\odot$, sun's upper limb.

6. Unclamp horizontal plate, and either with a slight motion, or, if plate be clamped, wholly with tangent screw, follow the sun's motion in azimuth till the sun's lower limb ($\subset$) becomes tangent to the intersection of cross-hairs, the vertical arc being untouched. Note the time and the reading on the horizontal arc.

7. The mean of the times and the mean of the azimuths will give the time and azimuth at which the vertical reading of the arc denotes the apparent altitude of the sun's centre $\odot$.

8. Correct apparent altitude, $\odot$.

Correction 1. For index error of instrument. Correction 2. For refraction, modified by barometric and thermometric readings; corrections to be found in tables in Frome's 'Surveying,' Drayson, or Chambers. Correction 3. For parallax. To be found in tables in 'Nautical Almanac,' and modified to noted altitude by formula :—Sin par in alt. = sin hor. par. × cos. alt.

9. Apparent altitude thus corrected gives true alt. $\odot$.

10. The true alt. $\odot$ subtracted from 90° gives the zenith distance ZS.

11. As the altitude of the elevated pole is equal to the latitude of the place, 90° minus latitude = zenith distance of the pole, viz. PZ.

12. The declination of the sun is given in the 'Nautical Almanac,' page 1, of each month, for each day at apparent noon. The variation of declination for each hour is also given, and the direction of declination, N. or S. Hence the declination at the time of observation is obtained. If the time of observation be 9 A.M., and declination increasing, the correction for three hours' variation must be subtracted from the declination at apparent noon, *vice versâ* if the declination be decreasing.

13. Then we have the three sides of the astronomical triangle to ascertain the angle Z, which is the measure of the angular deviation of the sun from the true meridian.

14. Compute the angle Z by the formula

$$\cos \frac{Z}{2} = \sqrt{\frac{\sin S \sin (S - PS)}{\sin PZ \sin ZS}}$$

where $S = \frac{1}{2}$ sum of the three sides of the triangle.

15. The magnetic bearing of the Δ station from which the sun's azimuth was taken should be noted two or three times with great care. If possible a stand to be used for the compass.

16. Then, knowing the sun's azimuth from a station and the direction of that station as regards the magnetic north, we get the deviation of the sun from the magnetic north. The computed angle, Z, is the deviation of the sun from the true north, and the difference of the two deviations is the variation of the compass.

17. Note that for afternoon observations the computed angle, Z, is to be subtracted from 360° before comparison with sun's magnetic bearing.

Annual Compass Variation.

The mean declination at Greenwich for 1920 was 14° 8′· 7 W. The average rate of decrease is 9′·5.

TO DETERMINE THE SOUTH BY MEANS OF A WATCH.

Point the hour hand of the watch at the sun, then half-way round (clockwise) between the hour hand and 'XII' on the dial points 'south.' Thus, suppose it to be 8 P.M., point the hour hand at the sun, then the 'IIII' of the dial points to south. In southern latitudes, to find 'north,' point 'XII' at the sun, then half-way round between 'XII' and the hour is due 'north.'

TO DETERMINE A TRUE EAST AND WEST.

This is easily obtained as follows :—Set up a *vertical* rod (any size) on a flat floor. Describe a circle round the base about twice (this varies with the latitude) the height of the rod. Some time in the forenoon mark the point where the shadow of the rod just touches the circle, and repeat this in the afternoon on the other side of the circle; mark this point also. A line through these points will be true east and west.

This method is a useful one for setting sun-dials, setting out buildings, etc.

As a guide to the true north, the following notes as to the whereabouts of the pole star at convenient hours in the evening or night will be useful, and correct enough for the purpose for the next hundred years.

The times given (Greeenwich mean time) are for the first day of each month, and become about 4 minutes (3 mins. 59·34 secs.) *less* every day.

45	48·996	42·503			90	0·000	0·000		

Length of a degree of longitude at $\phi°$ latitude $= \cos \phi_1° \times 69{\cdot}174$ statute miles; where $\tan \phi_1° = \frac{b}{a} \tan \phi°$; a = equatorial radius (3963·36 miles), and b = polar radius (3950·06 miles);

$\frac{b}{a} = \frac{3950{\cdot}04}{3963{\cdot}36} = {\cdot}99664.$

Example: What is the length of a degree of longitude at 50° latitude?

$\tan 50° = 1{\cdot}1917536$, therefore,

$\tan \phi_1° = {\cdot}99664 \times 1{\cdot}1917536 = 1{\cdot}1877493 = \tan 49° 54' 18''$; $\cos 49° 54' 18'' = {\cdot}6440569$ therefore length of degree $= {\cdot}6440569 \times 69{\cdot}174 = 44{\cdot}552$ statute miles.

Length of a degree of latitude at $\phi°$ latitude ($\phi°$ being at the middle of the arc) $= 69{\cdot}174$ $({\cdot}99330 + {\cdot}01005 \sin^2 \phi°) = 68{\cdot}711 + {\cdot}6952 \sin^2 \phi°$ statute miles.

Example: What is the length of a degree of latitude between 30° and 31°?

$\phi° = 30° 30'$, $\sin 30° 30' = {\cdot}5075384$, therefore length of degree $= 68{\cdot}711 + {\cdot}6952 \times {\cdot}5075384 \times {\cdot}5075384 = 68{\cdot}711 + {\cdot}179 = 68{\cdot}890$ statute miles. (*H. R. Kempe.*)

Example : From what distance will a hill 300 feet high be visible to an observer 20 feet above the sea ?

To an observer on the summit of the hill the horizon would be 19·9 miles distant, and to the observer in the example it would be 5·1 miles distant, hence two such observers facing one another would just see each other at a distance of 19·9 + 5·1 = 25 miles, which is therefore the distance the hill will be visible.

ASTRONOMY.

The Earth and Sun.

Equatorial radius of the earth = 6,378,200 metres (3963·30 miles) (*Helmert*) = 6,378,388 metres (3963·42 miles) (*Hayford*) ; mean value, 6,378,294 metres (3963·36 miles). Polar radius of the earth = 6,356,818 metres (3950·01 miles) (*Helmert*) = 6,356,909 metres (3950·06 miles) (*Hayford*) ; mean value, 6,356,864 metres (3950·04 miles).

Length of 1° of longitude = $6{,}378{,}294 \times \frac{2\pi}{360}$ = 111,322 metres (69·174 miles).

Equatorial horizontal parallax of sun (angle under which the equatorial radius of the earth would appear at the sun's centre) = 8″·80. Mean distance of sun from earth = $\frac{3963{\cdot}23}{\text{sine } 8''{\cdot}80}$ = $\frac{3963{\cdot}23}{{\cdot}000042664}$ = 92,890,000 miles. Maximum distance (1st July) = 93,950,000 miles. Minimum distance (1st Jan.) = 90,950,000 miles.

Angle under which the radius of the sun would appear at the earth's centre, at the earth's mean distance from the sun = 16′ 1″·18 (*Auwers*).

Radius of sun = $3963{\cdot}23 \frac{\text{sine } 16'1''{\cdot}18}{\text{sine } 8''{\cdot}8} = 3963{\cdot}23 \frac{{\cdot}0045699}{{\cdot}000042664}$ = 424,500 miles.

None of the foregoing numerical values can be accepted as absolute, as authorities are not agreed on the subject.

IDENTIFICATION OF STARS.

In stellar observations for time, latitude, or azimuth, the star selected for observation may be conveniently found from the following notes, which describe the relative positions of the larger stars in the constellations. The angular distance between two stars can be closely estimated by comparison with half the distance between the observer's zenith and the horizon—i.e. 45°.

(*a*) In the constellation *Ursa Major* the two well-known stars α and β (THE POINTERS) point directly to POLARIS, the Pole star. The latter also forms the end or tail of *Ursa Minor*.

(*b*) If the curve of the tail of *Ursa Major* be continued, about 30° along it will be found ARCTURUS (α *Boötes*).

(*c*) A line from POLARIS at right angles to the line from THE POINTERS gives 50° from the former, CAPELLA (*α Auriga*).

(*d*) A line from POLARIS through the last star but one of the tail of *Ursa Major* passes through SPICA, 30° beyond ARCTURUS.

(*e*) The POINTERS' line continued through POLARIS for 60° indicates THE GREAT SQUARE OF PEGASUS. The star in the corner opposite to the Pole is MARKAB.

(*f*) Midway between the SQUARE and POLARIS is the constellation *Cassiopeia* (five stars grouped like W).

(*g*) A diagonal through the SQUARE S.E. to N.W. produced 40° gives DENEB (*α Cygni*).

(*h*) 25° further and 10° to the right the same line gives VEGA (*α Lyræ*), a large white star.

(*j*) 35° south of DENEB and VEGA is ALTAIR (*α Aquilae*). This star is between two companions, and forms the apex of an isosceles triangle with DENEB and VEGA.

(*k*) A line from POLARIS through CAPELLA will touch RIGEL, 65° from CAPELLA. This line passes between ALDEBARAN (*α Tauri*), 10° west and 30° from CAPELLA, and BETELGEUSE, 10° east and 40° from CAPELLA. RIGEL and BETELGEUSE are diagonal stars in *Orion*.

(*l*) A line from ALDEBARAN through *Orion's Belt* passes near SIRIUS (*α Canis Majoris*) at an equal distance from ALDEBARAN. This is the brightest star in the heavens.

(*m*) 50° east of BETELGEUSE, forming nearly an equilateral triangle with BETELGEUSE and SIRIUS, is PROCYON.

(*n*) 30° north of PROCYON is CASTOR, and 5° S.E. of CASTOR is POLLUX.

(*o*) The apex of an isosceles triangle with CASTOR and PROCYON, 45° east, is REGULUS (*α Leonis*).

(*p*) Eastward from PROCYON to REGULUS 30° is DENEBOLA. DENEBOLA forms an equilateral triangle with ARCTURUS and SPICA.

ASTRONOMY IN FIELD WORK.

(*Fred. Simpson, A.M.I.C.E.*)

Choice of Instrument.

Choice of Instrument.—The most suitable instrument is the Transit Theodolite provided with a delicate level attached to the vernier arms of the vertical circle, and a sensitive striding level for use on the pivots of the horizontal axis. See figs. 119K, 119L, pp. 153-154. The adjustments must be made as perfectly as possible, and the residual index error carefully ascertained. The value of a division of each of the sensitive levels should be determined, and the position of the bubbles should be noted at the time of observing, and an allowance made for any variation in their readings. The most suitable form of diaphragm for astronomical work is that with simple vertical and horizontal cross hairs. For night work on stars it is necessary to illuminate the cross hairs, if the instrument is not provided with an illuminated axis; a lamp held a little distance in front of, and a little on one side of the object glass, may be used for this purpose.

With the ordinary eyepiece, altitudes exceeding 60° cannot be conveniently taken; for greater altitudes some form of diagonal attachment to the eyepiece is required. A makeshift arrangement can be improvised with a small piece of mirror held in the hand, or provisionally attached in front of the eyepiece at an angle of 45° to the axis of the telescope.

In observing the sun, a very convenient method, less trying to the eyes, is to cast the image of the sun and cross hairs on to a piece of white paper or card (to act as a screen) held about

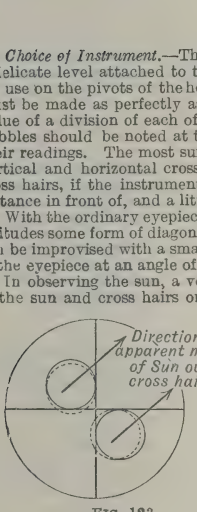

FIG. 123.

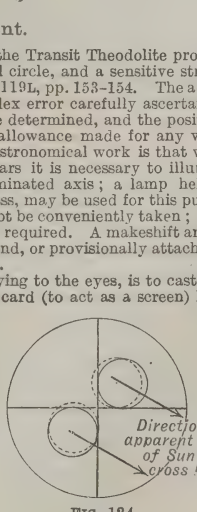

FIG. 124.

three or four inches from the eyepiece; the telescope must be focused for long-distance vision, with the cross hairs in focus; the telescope is then directed to the sun, and the eyepiece drawn out until perfect images of the sun and cross hairs are projected on the screen, the diameter of the image of the sun being smaller as the eyepiece is withdrawn. If the telescope inverts with direct vision, the image on the screen will be erect.

The limbs of the sun are observed when tangential to the respective cross hairs; the image of the sun should be allowed to leave one cross hair clamped a little in advance and followed with the other cross hair, using the tangent motion, so that the moving hair is brought tangential to the other limb as the first limb is just leaving the fixed hair; in this way only one hand is

occupied with the tangent motion. The correction for semi-diameter must be applied to the readings in altitude and azimuth. In the case of the altitudes, the correction for semi-diameter is applied as taken from the Almanac; in that of the azimuths, the correction to be applied to the horizontal circle reading is approximately the semi-diameter, taken from the Almanac, multiplied by the secant of the angle of altitude. These corrections apply to observations taken on any one limb of the sun to reduce the reading to the centre of the sun; but by taking the means of pairs of observations, on the upper and lower limbs for altitude, and on the right and left limbs for azimuth, the necessity for correction for semi-diameter is eliminated.

In a double observation on upper and lower and right and left limbs, a pair of observations are made, one in which the horizontal hair is fixed in advance, the vertical hair being moved by the tangent motion of the horizontal circle; the other observation is then made with the vertical hair fixed in advance, the tangent motion of the vertical circle being then used to follow the lower or upper limb with the horizontal cross hair, up to the time of the vertical hair, with the right or left limb which is being observed.

The cross hair which is being moved should always be kept slightly on the disc of the sun, up to the time of contact with the other hair, as it becomes indistinct when off the disc.

The means of the circle readings of the altitudes and azimuths taken in this way will be thus reduced to the centre, and will correspond to the mean of the times of observations, and no correction for semi-diameter is required.

Altitudes require correction for index error (+ or −), for refraction corresponding to altitude (always −), parallax (in case of sun or planets) corresponding to altitude (always +); semi-diameter in case of sun or planets, + if lower limb is observed, − if the upper; this correction is eliminated if observations on upper and lower limbs are combined.

Refraction.—The mean refraction values are near enough for ordinary purposes when the altitude observed is over 20°, but for lower altitudes a correction may be necessary, corresponding to the altitude, temperature, and barometric pressure; refraction decreasing with higher temperature and increasing with higher barometric pressure.

Parallax.—The horizontal parallax of the sun is approximately 9″, and for any given altitude = 9 × cosine of altitude, in seconds.

Declination as taken from the Almanacs must be corrected to correspond to the time of observation referred to time at the principal meridian adopted in the Almanac; generally it is sufficient to know his time to within ten minutes in spring or autumn, or within thirty minutes in summer or winter.

Latitude.

Latitude may be deduced from a single altitude of a star, or the upper or lower limb of the sun, when crossing the meridian. This altitude is corrected for index error and refraction in the case of a star; in that of the sun a further correction is required for parallax and semi-diameter to reduce the altitude to the sun's centre. The declination is corrected to the time of observation.

In the case of the sun, and of stars with declination less than the latitude if of the same name:—
Latitude = 90° − (altitude + declination), if declination is of the opposite name to latitude.
Latitude = 90° − (altitude − declination), if declination is of the same name as latitude.
In case of stars with declination of the same name, but greater than latitude:—
Latitude = (altitude + declination) − 90° at the upper transit.
Latitude = altitude + (90° − declination) at lower transit of circumpolar stars.

More exact determination of the meridian altitude can be obtained from a series of ex-meridian altitudes taken about the time of the star or sun's meridian passage, provided three altitudes are taken at equal intervals of time, or equal intervals of azimuth (it is immaterial what intervals are taken, but they must be equal and not extend more than about twenty minutes on either side of the meridian passage).

The corrected altitude at the meridian may be obtained by the following reduction:—

Subtract the lowest altitude from the other two and let these differences, reduced to seconds, be denoted by d_1 and d_2; then the meridian altitude will be = lowest altitude + $\frac{(4d_1 - d_2)^2}{8(2d_1 - d_2)}$ seconds.

EXAMPLE.—Three altitudes of the upper limb of the sun were taken at intervals of 6 minutes as follows:

	38° 10′ 35″	38° 12′ 40″	38° 12′ 30″
+ correction	2 17	− 38 10 35	− 38 10 35
= altitude on meridian, upper limb	38 12 52	2 05 = 125″	1 55 = 115′

$$\frac{(4 \times 125 - 115)^2}{8(2 \times 125 - 115)} = 137'' = 2' 17''.$$

Time and Azimuth.

Time and Azimuth from sun or star altitudes.

Let a = altitude observed (corrected for under error and refraction in case of star, as well as for parallax and semi-diameter in case of sun);

l = latitude;

p = polar distance = 90° − declination, if latitude and declination are of the same name, = 90° + declination, if latitude and declination are of different names.

$$s = \frac{a + l + p}{2};$$

then,

$$\log \sin \tfrac{1}{2} \text{ Hour Angle} = \frac{\log \sec l + \log \operatorname{cosec} p + \log \cos s + \log \sin (s - a)}{2}$$

$$\log \cos \tfrac{1}{2} \text{ Azimuth} = \frac{\log \sec a + \log \sec l + \log \cos s + \log \cos (s - p)}{2}$$

The Hour Angle in arc is reduced to time; if from a P.M. observation of the sun this will be Apparent Time P.M., but if from an A.M. observation this Hour Angle in time should be deducted from 12, the result being Apparent Time A.M. To arrive at Mean Time, the Equation of Time must be added or subtracted as directed in the Almanac, this Equation of Time being first corrected to correspond to the approximate time of the observation at the principal meridian to which the Almanac refers.

In star observations for time, the Hour Angle found and reduced to time is deducted from or added to the Right Ascension of the star (deducted from if before the meridian transit, but added to if after), this gives the Sidereal Time of observation. Take the Right Ascension of the Mean Sun for the previous noon from the Almanac, and correct this to the meridian of the place of observation; this deducted from the Sidereal Time of observation, and the difference reduced to Solar Time, will give the Mean Time of the observation.

	h. m. s.	h. m. s.
E.g., suppose Hour Angle found after transit of meridian		4 30 24
Right Ascension of star		8 10 43
Sidereal Time at observation		12 41 07
R.A. Mean Sun	1 35 28	
Correction for longitude 3 h. 54 m. West	+ 38	
		1 36 06
Interval in Sidereal Time from Mean Noon		11 05 01
Correction of interval, Sidereal to Mean Time		− 1 49
Mean Time of observation		11 03 12

The horizontal circle reading of the azimuth found as above should be corrected for the inclination of the horizontal axis of the vertical circle as denoted by the reading of the cross striding level; the difference of level in seconds of arc multiplied by the tangent of the altitude taken will give the correction to the horizontal circle reading this being added if the left-hand pivot is highest, and subtracted if the right-hand pivot is highest. The circle reading of some distant well-defined object should be used as a Reference Point to which the azimuth observed will then be connected.

In a series of observations where the sun has been utilised in the daytime, and it is desired to connect up a series of observations on stars, the adjustment of the instrument should be carefully gone over after sundown, and when the instrument has attained an even temperature, the Reference Point being utilised to check the results of the day observations with those of the night.

The degree of accuracy of the results will depend upon the care taken to eliminate slight errors in the data assumed or instrumental defects. In the case of observations for time, the taking of the mean of a combination of A.M. and P.M. observations will to a great extent eliminate the slight errors that may be due to instrumental defects, incorrect latitude assumed, or almanac corrections to date. The same remarks apply also to Azimuth except that the cross level error can only be eliminated by observations taken with reversed positions of vertical axis. In observations for latitude the errors of the instrument can be to a great extent corrected by taking the mean of meridian observations on stars to the north and to the south of the zenith.

EXAMPLE (in time and azimuth; P.M. observation). Data: latitude (l) 53° 29′ 05″ N.; corrected declination, 0° 35′ 13″ S.; corrected altitude of the sun's centre (a) 20° 37′ 18″; polar distance (p) 90° + 0° 35′ 13″ = 90° 35′ 13″.

Azimuth N. 121 47 00 W.

Azimuth from Greatest Elongation of Circumpolar Stars.

At instant of greatest elongation :—

$$\sin \text{Azimuth} = \cos d \sec l;$$
$$\cos \text{Hour Angle} = \tan l \cot d;$$
$$\sin \text{Altitude} = \sin d \operatorname{cosec} l.$$

The Hour Angle, reduced to time, is added to the Right Ascension of the star if the Greatest Elongation is to the west of the meridian, or subtracted if to the east; this will give the Sidereal time of the Greatest Elongation. The sidereal time of the mean sun's passage of meridian for the succeeding noon subtracted from this will give the sidereal interval of time from noon, which, reduced to mean time, will give the Mean Time of Greatest Elongation. The altitude at Greatest Elongation is useful in setting the instrument for the observation.

Without knowledge of the latitude the Azimuth may be obtained from two observations on stars, one to the east, the other to the west of the meridian, and from the horizontal angle between them, which will be the sum of their Azimuths. Let this angle be denoted by $A + A_1$), and let d and d' be the respective declinations of the stars used, then,

$$\tan\left(\frac{A - A_1}{2}\right) = \tan\frac{d + d_1}{2} \times \tan\frac{d - d_1}{2} \times \tan\left(\frac{A + A_1}{2}\right),$$

giving the half difference of Azimuths, which added to and subtracted from the half sum of Azimuths will give A and A, respectively. The latitude can then be computed from one of the Azimuths and found by formula

$$\cos l = \cos d \operatorname{cosec} A.$$

EXAMPLE.—Taking stars β Crucis (d_1 = 59° 06′ 30″S.); γ Hydri (d = 74° 33′ 59′ S.); angle between their Greatest Elongations 57° 33′ 33″ (= A + A_1).

$\frac{d + d_1}{2}$ =	66° 50′ 14½″	l tan 0·36874
$\frac{d - d_1}{2}$ =	7 43 44½	l tan 9·13264
$\frac{A + A_1}{2}$ =	28 46 46½	l tan 9·73980
$\frac{A - A_1}{2}$ =	9 53 05	l tan 9·24118
	± 28 46 46½	
Greatest Elongation γ Hydri	18 53 41½	
" " β Crucis	38 39 51	

The latitude may then be calculated as follows, from γ Hydri :—

Azimuth	18° 53′ 41½″	l cosec	0·48968
d	74 33 59	l cos	9·42508
		l cos	9·91476

latitude = 34 43 55 S.

To reduce Mean Solar Time intervals to Sidereal Time intervals (approximate).

Reduce interval into hours and decimals of an hour, multiply by 10 and diminish product by $\frac{1}{70}$; the result will be correction in seconds to be *added* to Mean Time interval.

	h. m. s.	
EXAMPLE.	16 30 18 M.T.	16·505 × 10 = 165·05
Correction	+ 2 42·7	$-\frac{1}{70}$ 2·36
	16 33 00·7 Sidereal T.	162·69 sec.
		= 2 m. 42·69 sec.

To reduce Sidereal to Mean Time intervals.

Reduce intervals into hours and decimals of an hour, multiply by 10 and diminish product by $\frac{1}{60}$; the result will be correction to be *subtracted* from Sidereal Time interval.

	h. m. s.	
EXAMPLE.	16 33 00·7 Sid. T.	16·5502 × 10 = 165·50
Correction	− 2 42·7	$-\frac{1}{60}$ 2·76
	16 30 18 M.T.	162·74 sec.
		= 2 m. 42·74 sec.

The error in using these approximations will be less than $\frac{1}{10}$ second in a 24-hour interval.

Longitude by Moon Culminating Stars.

This is the most convenient method for determining the longitude when the Mean Time at Greenwich is not accurately known, the only requirements being a well adjusted transit theodolite, a watch whose rate can be depended upon for a short interval of time but whose actual error need not be known, and a Nautical Almanac.

The moon varies comparatively rapidly in Right Ascension (R.A.), but its R.A. at the instant of its transit across the plane of the meridian can be accurately determined by comparing its time of transit with that of a star or stars which pass the meridian about the same time.

The theodolite is adjusted with its line of collimation in the plane of the meridian by the aid of one of the methods before described for obtaining azimuths ; the times of transit, over the centre thread, of the selected stars of reference and the moon's bright limb are carefully noted.

The intervals (reduced to Sidereal Time) between the times of transit of the respective stars and the time of transit of the moon's bright limb, added to the R.A. of the respective stars (in the case of stars which transit before the moon), or subtracted from the R.A. of any stars which transit after the moon, will give the R.A. of the moon's bright limb at the instant of its transit over the meridian.

We have, under the heading of ' Moon Culminating Stars,' the R.A. of the moon's bright limb at its transit at Greenwich, and also the variation of the moon's R.A. in one hour of longitude expressed in seconds ; the difference between the R.A. of the moon's bright limb when passing the meridian of Greenwich and the R.A. as found when passing the meridian at the place of observation gives the change of R.A., and this difference (reduced to seconds), being divided by the variation corresponding to one hour difference of longitude, will give the difference of longitude between Greenwich and the place of observation expressed in hours and fractions of an hour.

Under the same heading of ' Moon Culminating Stars ' will be found convenient pairs of stars which transit within half an hour or so of the time of transit of the moon and which have a declination nearly that of the moon so that a slight movement of the telescope of the instrument

in altitude will bring them within its field. As these stars are generally of small magnitude and not easily distinguishable it is advisable to (approximately) calculate the altitude at which they cross the meridian ; the instrument may then be set in advance so that the star will cross approximately in the centre of the field. Any of the stars catalogued in the Nautical Almanac of greater magnitude, and easily distinguishable, may be used, but their declination and R.A. should not differ much from those of the moon.

When the longitude of the place of observation differs considerably from that of Greenwich, the ' variation for one hour ' given in the tables should be corrected by interpolation to correspond to the approximate middle interval of time between the transit at Greenwich and that of the observed transit.

Let

t_1, t_2 be the observed times of transit of the star and the moon's bright limb ;

RA_1, RA_2 be the Right Ascensions of the star and the moon's bright limb taken from the catalogue ;

c the hourly variation (corrected, if necessary, to the middle time) ;

then the longitude in time $= \dfrac{(t_1 - t_2) - (RA_1 - RA_2)}{c}$,

the interval $(t_1 - t_2)$ if in Mean Time must be reduced to Sidereal Time,

$(RA_1 - RA_2)$ must be expressed in seconds,

the longitude will be expressed in hours and fractions of an hour, and to the west if positive and to the east if negative.

Timing Observations.

When working with an assistant the time may be noted at the instant a signal is given by the observer, but when observing alone it is difficult to note the exact time of contact or transit on watch or chronometer when the hands are employed in manipulating the instrument and the eye engaged in taking the sight.

In this case a convenient method is to use a watch whose time of beat is known (in modern watches usually $\frac{1}{5}$ second) ; this watch should be in such a position that the beats are distinctly heard, for example, suspended over the ear from the cap, in a small bag or watch pocket. The beats are then counted from the instant of contact or transit and continued until the seconds finger of the standard timepiece can be noted on some convenient second ; this time noted, less the number of beats of the auxiliary watch, reduced to seconds and fractions, will be the actual time of the observation.

As probably some little time may elapse after the observation before the standard timepiece can be read, especially at night where a lamp has to be used, this extended counting of beats of say $\frac{1}{5}$ second becomes difficult when arriving at the double syllable numbers ; but by adding a ' dummy ' syllable to the first twelve counted and then continuing with ' thir-teen,' ' four-teen,' and so on, giving one syllable to each beat, the counting of $\frac{1}{5}$ seconds becomes quite easy, even if carried to 100 beats and over, e.g taking the dummy syllable as ' and,' and starting the instant of observation with ' nought,' the counting would continue :—' nought-and,' ' one-and,' ' two-and,' ' three-and,' . . . ' 'leven-and,' ' twelve-and,' ' thir-teen,' ' four-teen,' . . . ' twen-ty,' ' twent'-one,' and so on. Then taking the first syllable as units and the second syllable as half, the counted beats multiplied by 4 and divided by 10 will give the required intervals in seconds and tenths, in the case of the auxiliary watch beating fifths of seconds.

Taking examples, say the beats counted between the instant of observation and the time noted on the timepiece was on the first syllable to thirty-seven, the time at that beat being 3 hrs. 47 mins. 15 secs. ; then the interval to be deducted would be $\dfrac{37 \times 4}{10} = 14{\cdot}8$ seconds.

and the corrected time of the observation would then be 3 hrs. 47 mins. 15 secs. $- 14{\cdot}8$ secs $= 3$ hrs. 47 mins. $0{\cdot}2$ secs. In another case, say the second syllable of ' nine-and ' corresponded to 6 hrs 23 mins. 55 secs. on the timepiece, the correction would then be $\dfrac{9\frac{1}{2} \times 4}{10} = 3{\cdot}8$ seconds,

and the corrected time of observation 6 hrs. 23 mins. 55 secs. $- 3{\cdot}8$ secs. $=$ 6 hrs. 23 mins. $51{\cdot}2$ secs.

This method of measuring short intervals of time is useful in other instances ; for example, in estimating distances by the velocity of sound, etc.

GRAPHIC METHOD OF FINDING TIME AND AZIMUTH FROM ALTITUDE OF SUN OR STAR.

Describe a circle, fig. 125, of any convenient radius through the centre O; draw diameter MOM. From O draw PO making angle POM equal to the latitude; draw OQ at right angles to PO. Through O draw OA, making AOM equal to the corrected altitude, and OD, making DOQ equal to the corrected declination, and on the side of OQ towards P if the declination and latitude are of the same name, or on the opposite side if of different names.

Through A draw AA, parallel to MM, and through D draw DD, parallel to QO, intersecting AA_1 in S.

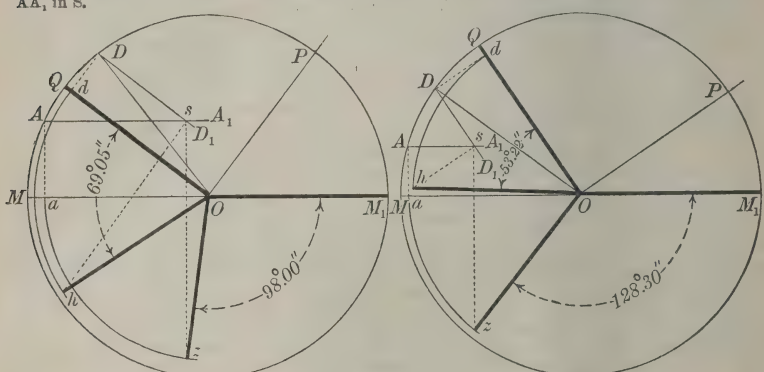

FIG. 125.

Data.	Result.	Data.	Result.
Lat. 53° 30′ N.	Azimuth N. 98° 00′ W.	Lat. 34° 30′ S.	Azimuth S. 128° 30′ W.
Dec. 14° 50′ N.	Hour Angle 69° 05′	Dec. 19° 50′ N.	Hour Angle 53° 22′
Alt. 24° 20′ P.M.		Alt. 15° 40′ P.M.	

To find the Azimuth.

Drop a perpendicular from A to OM, intersecting this latter in a; from centre O and radius Oa draw arc az, and from s draw sz perpendicular to MOM_1, intersecting arc az in z; through z draw Oz. Then the angle M_1Oz will represent the azimuth from the elevated pole east or west of the meridian according as the time (A.M. or P.M.) at which the observation was made.

To find the Hour Angle.

Draw Dd at right angles to QO, and with centre O and radius Od draw arc dh; from s draw line sh perpendicular to QO, intersecting arc dh in h; draw line Oh. Then QOh will be the hour angle at the time of observation before or after apparent noon.

This diagrammatic method may be utilised for approximate determination of other problems, such as azimuth and time of sun or stars at instant of rising or setting; altitude and azimuth at a given time; or for altitude and time of passing prime vertical.

GEODETIC FORMULÆ.

From measurements made of various meridians and parallels it has been found that the earth has the form of an ellipsoid of revolution with its greatest diameter at the equator and its least between the poles; and that the radius of curvature of the meridian varies with the latitude, being least at the equator and greatest at the poles, so that the length of a degree of latitude is more at the poles than at the equator. The length of a degree of longitude varies also with the latitude, being greatest at the equator and zero at the poles.

In treating with measurements of an extensive character over the surface of the earth, it is necessary to take into account its ellipsoidal shape, and it is convenient to employ certain approximations, so that spherical trigonometry may be used in the solution of the problems involved. The following formulæ enable the radius of a spherical surface to be found that approximates most nearly to the ellipsoidal surface embracing the area under consideration.

In these formulæ

a = the equatorial radius of the earth; e = the eccentricity; ϕ = the mean latitude; A = the azimuth.

$$\text{Radius of curvature of meridian} = Q = \frac{a(1-e^2)}{\sqrt{(1-e^2\sin^2\phi)^3}}.$$

$$\text{Radius of curvature of normal section perpendicular to meridian} = N = \frac{a}{\sqrt{(1-e^2\sin^2\phi)}}.$$

Radius of curvature of a normal section which cuts meridian at an angle A

$$= \frac{QN}{Q \sin^2 A + N \cos^2 A}.$$

Radius of curvature of an area of the earth's surface, or mean curvature $= \sqrt{QN}$.

Radius of a parallel of latitude $= N \cos \phi = \frac{a \cos \phi}{\sqrt{1 - e^2 \sin^2 \phi}}$

The logarithms of the most probable values of the constants used above are as follows (taking a in statute miles):—

$$\log. a = 3{\cdot}59806. \qquad \log. e^2 = 7{\cdot}83047. \qquad \log. (1 - e^2) = 9{\cdot}99853.$$

Adopting the radius which most nearly corresponds to the surface considered at the mean latitude ϕ, any measured length l on this surface may be reduced to arc by one of the following formulæ, ρ being the radius adopted reduced to the same unit as l:—

$\frac{l \times 57{\cdot}2958}{\rho}$ in degrees of arc; $\frac{\times 3437{\cdot}747}{\rho}$ in minutes of arc; $\frac{l \times 20626{\cdot}5}{\rho}$ in seconds of arc.

The table on page 163, 'Length of a Degree in Latitude and Longitude,' is calculated from the accepted dimensions of the earth. Values for intermediate latitudes may be obtained from this table, by interpolating, with sufficient exactitude for most purposes. The length of a degree on a great circle at right angles to the meridian at a given latitude may be obtained by multiplying the length of a degree of longitude (as taken from the table) by the secant of the latitude.

Convergence of Meridians.

In traverses and route surveys, a survey line is referred to a meridian at a certain point crossing the meridian with an azimuth A, this line, if continued in the same direction, having increased or diminished azimuths. The differences of azimuth can be approximately determined by calculating the convergence of the meridian corresponding to a given unit departure at the mean of the latitudes, and multiplying this by the departure as calculated from the traverse. To obtain the azimuth on crossing the second meridian, the convergence obtained in the manner just explained is added to or subtracted from the azimuth crossing the first meridian, being added where the latitude is increased and subtracted where the latitude is diminished.

The convergence, corresponding to various unit lengths of departure, may be calculated by the following formulæ, with sufficient approximation for use in ordinary traverse surveying. The length of a degree of longitude corresponding to the mean latitude is taken in miles from table, page 163, interpolating if necessary; then:—

Log. of convergence in seconds per mile of departure
$= \log. \sin \phi + 3{\cdot}55620 - \log.$ miles per 1° longitude.

Log. of convergence in seconds per 1,000 feet of departure
$= \log. \sin \phi + 2{\cdot}83367 - \log.$ miles per 1° longitude.

Log. of convergence in seconds per 1,000 metres of departure
$= \log. \sin \phi + 3{\cdot}34966 - \log.$ miles per 1° longitude.

To range a parallel of latitude by setting out chords of a given length:—

The chords are ranged making an angle to the meridian of 90° half the angle of convergence corresponding to the length of the chord at the proposed latitude. The succeeding chords will have an angle of deflection from the preceding chord produced, equal to the convergence corresponding to the length of chord used.

To range a parallel of latitude by means of offsets:—

A line is run, perpendicular to the meridian, then the lengths of offsets are equal to the distances along this perpendicular line multiplied by the sine of half the angle of convergence corresponding to the lengths.

If the offsets are equidistant the length of the second offset will be four times the length of the first; the third, nine times the first, and so on; the n^{th} offset will be n^2 times the length of the first.

Horizontal Sun Dial.

On a line NS, fig. 125A, mark off a convenient length NO: from O set off a line towards L, making an angle NOL equal to the latitude of the position (taken in diagram 53° 30′), and from N draw a perpendicular to OL, cutting the latter in point L. From N and with length NL mark off a point C in the line NS, and with C as centre and the same length NL as radius describe the quadrant NQ and join NQ with a straight line.

Divide the quadrant NQ into six equal parts (each corresponding to one hour) and from these divisions on the arc draw lines towards the centre C and mark the points at which these radial lines cross the line NQ.

From O draw a line perpendicular to NS and mark off OE equal to CQ and join NE.

From each division on line NQ draw a line parallel to NS, marking where this line crosses the line NE in each case.

Then lines drawn from O through each of these points, marked off in NE, will be the dial lines corresponding to the hour divisions on the quadrant from which they were found respectively.

Having completed the divisions of one quadrant, these angles may be transferred to the other quadrants but in reverse order (VI–VII equals VI–V, VI–VIII equals VI–IIII, and so on).

An allowance must be made for the thickness of the style between the AM and PM portions of the dial, the AM dial being exactly similar to the PM dial but drawn with the XII lines the thickness of the style apart.

The style is constructed with the angle of inclination of the inclined face equal to the latitude of the site, its lower point at O and its upper towards the elevated pole, so that its

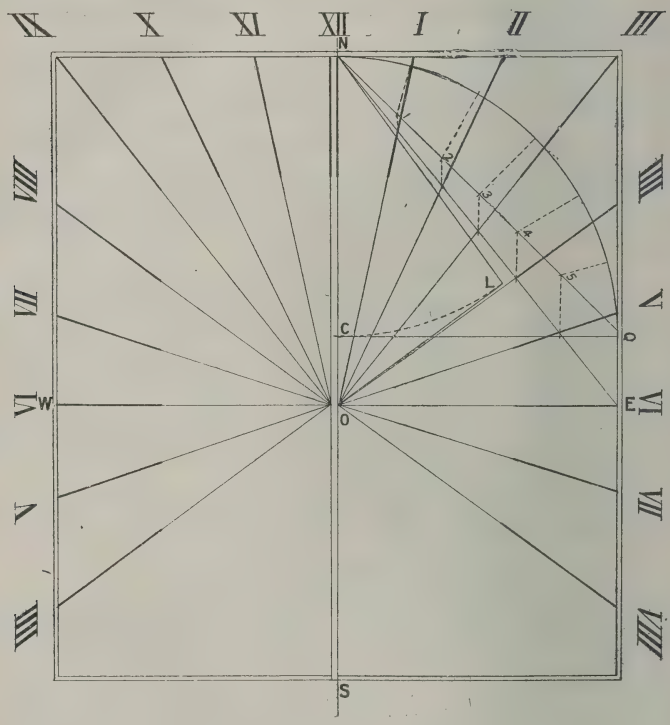

FIG. 125A.

plane is in that of the meridian, the XII (noon) lines pointing towards the north in northern latitudes or towards the south in southern latitudes, and the VI–VI lines pointing east and west, so that the upper face of the style will be parallel to the Polar axis. The plane of the dial should be perfectly level.

(Methods of fixing the direction of the true north and south line will be found on page 162.)

The time indicated by the dial is sun time, and to get mean time the table of Equation of Time, page 162, should be applied as there directed. To arrive at standard time a constant correction must be applied according to the difference of longitude between the dial and the standard meridian (Greenwich in Great Britain) adopted in the country (subtracted if to the east or added if to the west).

The dial angles may be calculated if preferred by formula :

$$\tan t = \sin l \tan h ;$$

where

t = angle at O from NO to the hour line on dial corresponding to h ; l = latitude of position

h = hour angle.

DRAWING.

(H. A. Miles.)

Engineering drawings are usually required for one of two purposes, viz. as illustrations or for workshop use. The former, which are not necessarily to scale, or dimensioned, may be either 'line' or 'wash' drawings—the first for preference—or prepared from photographs in the following manner A bromide print is outlined and worked up with waterproof ink, after which the photographic image is bleached out. This is useful in complicated perspective views, or where the skill of the draughtsman is not equal to elaborate freehand work.

For reproduction purposes, drawings should always be prepared to an enlarged scale—twice full size is usual. If a scale is necessary it should be *drawn* (not denoted in words), so as to be reduced proportionately with the illustration to which it refers. Bold and striking effects should be aimed at, simplicity rather than elaboration being most effective. Shade lines and dotted hidden details are both useful, and surface lining, B, fig. 126, is sometimes necessary, but care must be taken to avoid overcrowding. A good rule is never to introduce a superfluous line or to omit one which is necessary.

The best material is 'Turkey Mill' paper or 'Bristol Board,' but it is sometimes advantageous to use tracing cloth, and (provided it is not yellow) good results will be secured with this. The blackest of black ink should be employed. All artists' colourmen now stock the liquid carbon or waterproof ink, and process black, either of which will be found suitable.

For workshop purposes a drawing should be looked upon as a book explaining the designer's views—it should be easily 'read' by the mechanic, and must contain all information necessary for the construction of the item represented. To this end there are certain conventions generally

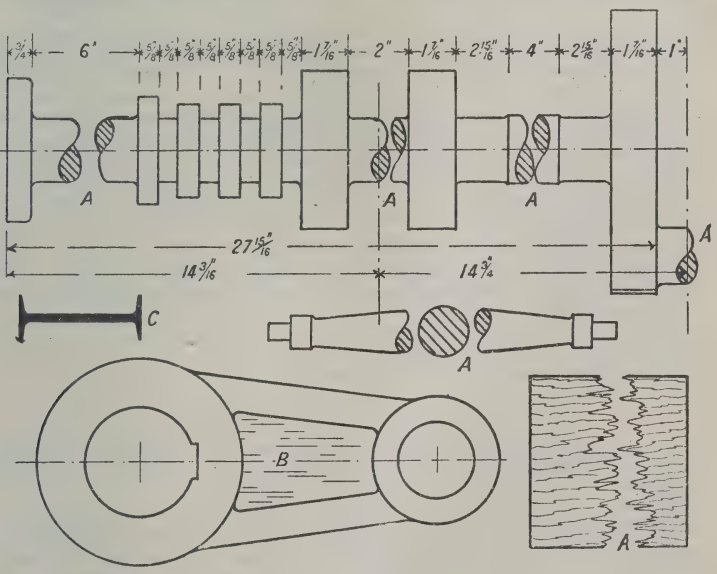

FIG. 126.

employed, and in the same shop these always mean the same thing, but unfortunately, owing to the absence of a recognised standard, each firm is at liberty to please itself, and consequently there is no uniformity.

The conventions which follow are those most frequently employed :—

Construction and visible boundaries . . . .

Ditto hidden from view .

Centre or pitch lines .

Projection lines . . .

Dimension lines . . . 1′. 3″

One view of an article is seldom sufficient for a proper understanding of its construction and plans, elevations and sections are usually given, minor details being generally drawn separately and frequently to an enlarged scale.

All such drawings should be fully dimensioned. Where a number of small dimensions combine to make up a total, the overall should be given, not only to save time, but to act as a check upon the others.

Where coloured drawings are desired to indicate sections, the following will meet requirements :—

Cast iron	Neutral tint or Payne's grey.
Wrought iron	Prussian blue.
Steel	Violet carmine.
Copper	Crimson lake, little gamboge.
Brass	Gamboge, little burnt umber.
Lead	Indian ink and Prussian blue.
Brickwork	Light red, little crimson lake.
Wood	Yellow ochre and burnt sienna.

In each case the section is coloured a considerably deeper shade of the same tint than the other parts of the drawing.

In building plans (otherwise uncoloured) prepared to show alterations or additions to existing premises, it is a common practice to colour new work red.

Different methods of lining are sometimes employed to represent different materials, but if followed to any extent this is likely to lead to mistakes unless supplemented by a key or written explanation, in which case it can scarcely be considered necessary.

A very general practice is to adopt C (fig. 127) for all metals ; to line up woodwork in imitation of the grain A (fig. 127) ; and to use as few others as possible—the material being specified in words thus :—' Brass '—' Copper 75 mils '—' Spring Steel 22 S.W.G.'—etc.

It is obviously impossible to fix any definite spacing between the lines. Small details must necessarily be treated differently from larger surfaces, and very large areas need only be sectioned around their boundaries.

Typical specimens of various section conventions are shown in fig. 127. Where two pieces of material butt against each other, the section lining should run in opposite directions ; if three meet, the lines running in the same direction should break joint. (D, fig. 127.)

Small or thin sections such as boiler plates, engine beds, girders, joists, etc., may be blacked in solid. (C, fig. 126.)

Long details such as columns, shafting, pipes, etc., need not necessarily be shown full length, and in such cases break lines, A, fig. 126, are employed. Should the diameter vary, one or more sections may be shown, as in the firebar example.

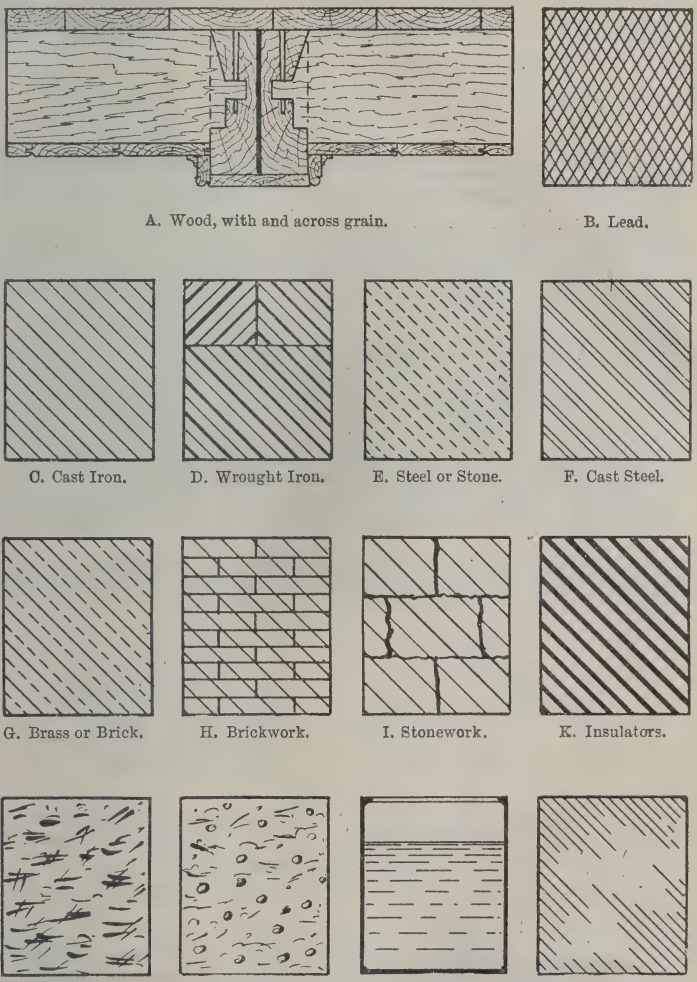
For PHOTO-COPYING OF DRAWINGS see Index.

Patent Specification Drawings.

All necessary information will be found in a pamphlet entitled ' Instructions to Applicants for Patents,' published by and obtainable free on application at the Patent Office, 25 Southampton Buildings, Chancery Lane, London, W.C., or it will be sent free on receipt of 1*d.* for postage.

One point to remember in this class of work is that the 13-inch side of each sheet is bound up with the specification, and should be looked upon as the left-hand side. All lettering, etc., should therefore be upright, viz., not facing different ways.

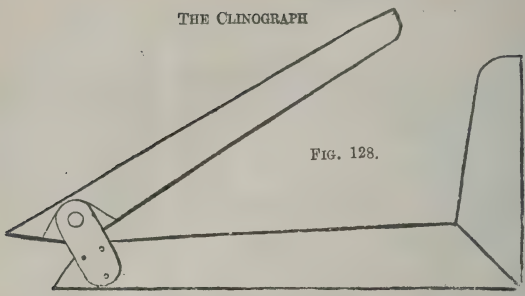
For whatever purpose drawings are prepared, they will inevitably indicate to the expert eye the character of the draughtsman. One man scarcely varies the thickness of his lines, muddles his lettering, and does not space his work out to advantage. Another has the knack of ' displaying ' his work, as a printer would say ; his construction lines are bold and the others thin, his lettering varies according to whether it is of major or minor importance—heavy block, small capitals, or small italics being used as considered advisable ; all his details are nicely spaced, and the whole effect is one of neatness, clearness, and completeness.



A. Wood, with and across grain.
B. Lead.
C. Cast Iron.
D. Wrought Iron.
E. Steel or Stone.
F. Cast Steel.
G. Brass or Brick.
H. Brickwork.
I. Stonework.
K. Insulators.
L. Earth.
M. Concrete.
N. Water.
O. Glass.

FIG. 127.

THE CLINOGRAPH



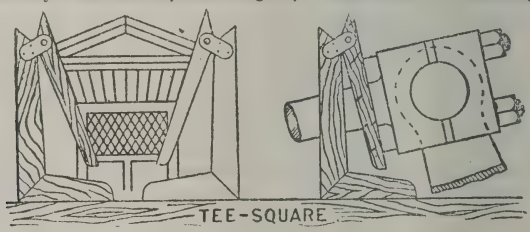


FIG. 128.

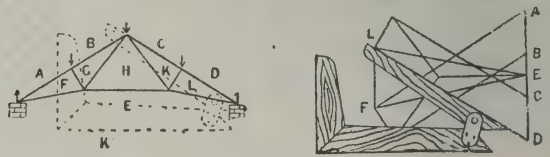
This instrument, figs. 128, 129, 130 (*Harrison's Patent*), manufactured by Messrs. W. H. Barling, is a set square with a swivelling blade, used in conjunction with a tee-square, for drawing lines parallel, perpendicular, or symmetrically inclined to any given line or direction.



With one edge of the instrument resting against the edge of the tee-square, the blade can be instantly set to the required position, and the friction of the joint is sufficient to hold it firmly while in use.

For drawing parallel lines it is slid along the tee-square to any part of the drawing paper. For perpendicular or symmetrical lines, after being set, it is turned with its other edge against the tee-square, or with its other face on the paper, as the case may be, after which it is slid into any position as before. As one edge always rests against the tee-square, the discomfort attending the ordinary methods of drawing inclined lines is avoided, and such work is greatly facilitated, whilst at the same time greater accuracy is secured. The instrument is made in pearwood, mahogany, and mahogany with ebony edges, and transparent celluloid, in three sizes, 7 ins., 9 ins., and 12 ins.

Used for symmetrical figures. Used in machine drawing.

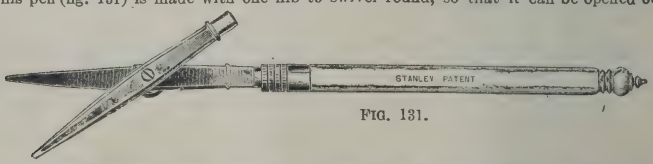
FIG. 129.

Used for graphic statics.

FIG. 130.

STANLEY'S PATENT DRAWING PEN.

This pen (fig. 131) is made with one nib to swivel round, so that it can be opened out for clearing, the arrangement being such that it locks back again in exact position, and the adjustment for the thickness of line is not interfered with.



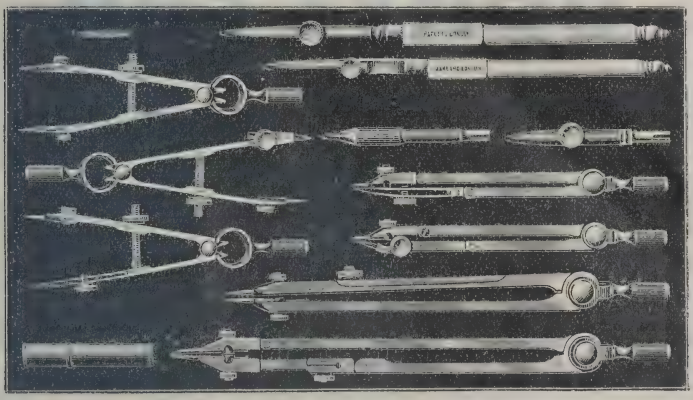


FIG. 131.

Modern Style, British Made Drawing Instruments of the highest quality and finish.

Manufactured in London by W. H. HARLING. *Established* 1851.

Seventy years experience are behind these instruments and every piece is guaranteed.

B.E. 110 STANDARD SET, as illustrated, containing: Half-Set and Lengthening Bar; Hair Spring Divider; Bow Pen; Bow Pencil; Three Spring Bows; Two Drawing Pens, with aluminium handles; Case of Leads; Two Spare Needles and Key, in neat Wallet Case .. .. £ 4 10 6

THE SAME SET, fitted with square ivory handle Pens and centre screw Spring Bows .. .. £ 4 18 0

You should see Harling's New Quick Set Drawing Pen.

Particulars on request.

Illustrated Catalogue giving particulars of Sets from 20/- value, and separate Instruments, will be sent on receipt of business card.

A Steel Drawing-board Edge.

One of the difficulties a draughtsman quite frequently bumps up against is that of trying to draw long lines parallel to each other. When drawn, he often finds that, instead of being parallel throughout, they are from $\frac{1}{16}$ to $\frac{1}{4}$ in. farther apart at one end than the other. This condition is almost surely to be found in steam-heated offices, where the cross-grained end of the board is depended upon to make a straight edge upon which the head of the T-square is expected to slide.

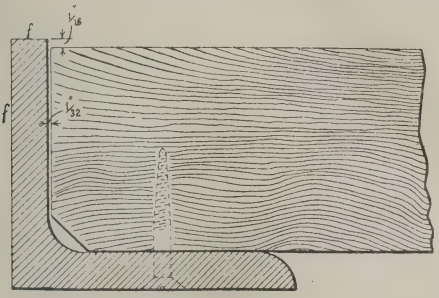

Fig. 132.

Fig. 132 shows an arrangement fitted to a board to overcome this difficulty, and found to answer the purpose admirably. The straight edge is made from a piece of angle iron 2 by 2 by $\frac{1}{4}$-in. ground or otherwise finished on the top and outside edges to ensure its being perfectly straight. The top edges project about $\frac{1}{16}$ in. above the surface of the drawing-board to give the T-square clearance above the drawing-pins when sliding up and down, and small particles of dirt are thus prevented from being ground into the paper. The angle iron is fastened to the drawing-board by two wood screws about $1\frac{1}{2}$ in. long, screwed in about 5 ins. from each end of the angle iron. The screw hole in one end should be slightly slotted to take care of swelling and shrinking of the wood. (*W. F.*, '*Machinery.*')

Kink for Draughtsmen.

Draughtsmen who find that the jaws of the lead-holding clamp of a compass have become so smooth that it is difficult to tighten them sufficiently to hold the lead, can easily overcome this difficulty in the following way. First remove the clamping screw and insert a tap in place of the lead; then press the jaws together gently with the fingers and run the tap backwards and forwards five or six times, this will roughen the jaws so that they will grip the lead firmly.

(*O. T. R.*, '*Machinery.*')

FIG. 133

Melting Points of Chemical Elements.

The following table gives the melting points of chemical elements and is reproduced from a circular issued by the U.S. Bureau of Standards. The value of the melting points used by the Bureau as standard temperatures for the calibration of thermometers and pyrometers are indicated in italics. The other values have been assigned after a careful survey of all the available data.

Element.	°F.	°C.	Element.	°F.	°C.

(*Parkes and Martin.*)

MELTING POINTS OF THE CHEMICAL ELEMENTS.

The following are the melting points in C.° on the thermo-dynamic scale used by the Washington Bureau of Standards as standard temperatures in the standardisation of thermometers and pyrometers :—Mercury 38·9°, tin 231·9°, cadmium 320·9°, lead 327·4°, zinc 419·4°, antimony 630·0°, aluminium 658·7°, silver 960·5°, gold 1061·0°, copper 1083·0°, nickel 1452°, iron 1530°, palladium 1549°, platinum 1755°, tungsten 3000°. At temperatures of 1000° the uncertainty is of the order 0·1°, for platinum 5°, and for tungsten 100°. A further table of other standard temperatures is given in which the following are included :—Normal boiling point of oxygen 183·0°, sublimation of carbon dioxide in an inert liquid 78·5°, normal boiling points of water 100°, naphthalene 217·96°, benzo-phenone 305·9°, sulphur 444·6°, freezing point of sodium chloride 801°.

In the *Physical Review* the melting-point in C.° of rhodium is estimated to be at 1907° or 1968°, and that of iridium at 2292° or 2388°. That of silicon is placed at 1434° or 1452°, and that of palladium at 1548° or 1576°. The reason for two figures being given in each case is due to the fact that the calculations are based on different estimates of the melting-point of platinum, which has been placed at 1745° by some experimenters, and at 1789° by others.

MELTING POINTS OF REFRACTORY MATERIALS.*

The melting-points in C.° of various samples of fire-brick, as determined in an electric vacuum furnace, the temperature being measured with an optical pyrometer, were as follows :—Kaolin, 1740° ; pure alumina, 2010° ; pure silica, 1600° ; bauxite, 1820° ; bauxite clay, 1795° ; chromite, 2180° ; magnesite brick, 2165°. (*W. M. Barr, in 'Industrial Engineering.'*)

* See also 'Refractory Materials,' page 426.

The salt should be thoroughly dissolved, or the results will not be satisfactory. Calcium chloride is said to be superior to sodium chloride in that it does not corrode steel tanks and barrel hoops. Where calcium chloride is used, the wooden barrels should first be well coated inside with asphaltum, or a mixture of crude paraffin and resin, to prevent the shrinking of the staves and subsequent leakage.

Glycerine is recommended for use in chemical fire extinguishers. It has no effect upon metals, but has a tendency to disintegrate rubber. It has been stated, however, that the continued use of glycerine in water renders it liable to a decomposition that would develop compounds having a corrosive action on metals. The following proportions may be used :—

Glycerine, pounds per gallon	3½	5½	(One gall. of glycerine
Temp. solution will withstand	+ 10° F.	− 10° F.	weighs 10½ lbs.)

Denatured alcohol has advantages over both glycerine and calcium chloride, in water solutions, as it has no injurious effect on either metal or rubber. A solution of about 50 per cent. is inflammable, but it would rarely be necessary to have a solution of over 30 per cent.

A 20 per cent. solution freezes at + 10° F. | A 40 per cent. solution freezes at − 20° F.
30 „ „ „ − 5° F. | 50 „ „ „ − 35° F.

Freezing Temperatures.

Sea water, −2·5° C., 27·5° F.; Mercury, −38·8° C., −37·8° F.; Acetone, −95° C., −139° F.; Pratt's petrol spirit, −128° C., −198° F.

Temperature of the Atmosphere

diminishes according to the height above the earth's surface. In the Temperate Zone a diminution of 1° C. corresponds in the mean to an ascent of 180 yards. As the mean of a series of observations made during balloon ascents, a diminution of 1° C. corresponded to an increase in height of 232 yards.

According to Kropotkin, the temperature above the earth's surface decreases 3° to 5° F. for each 1,000 ft. The average temperature at an altitude of 20,000 ft. is 13° below 0° F.; at 25,000 ft. it is 35° below 0° F.; these low temperatures prevail all the year round. The ratio of decrease in temperature, which is 3° F. for each 1,000 ft. at the lower strata, is twice as great at the highest levels, but varies from summer to winter to the extent of about 20° F. (See also page 1069.)

The Mean Daily Temperature is that obtained by adding together twenty-four hourly observations and dividing by 24, the temperature being taken of the air, and not of the ground. The temperature of a month is the mean of those of thirty days, and the temperature of the year is the mean of those of twelve months. The mean temperature of London is 8·28° C., or 46·9° F.; the mean in summer is 62° F., and in winter 40° F.

Temperature of Seas and Lakes.

The temperature of the sea under the Torrid Zone is always about 26° to 27° C. at the surface; it diminishes as the depth increases, and in temperate as well as in tropical regions the temperature of the sea at great depths is between 2·5° and 3·5° C. The average winter temperature of the sea round the coast of England is higher than that of the land. The mean annual temperature of the surface of the sea round England is 49° F.; the mean surface temperature of the Indian Ocean is 89° F., and of the Red Sea 94° F. The temperature of lakes at their surface may be 20° to 25° C. in summer; the temperature of the bottom, 4° C., which is that of the maximum density of water. The Great Geyser, in Iceland, at a depth of 66 feet, has a temperature of 124° C.

Temperature of the Earth.

The average increase in temperature is 1° C. for every 27·4 metres of descent, which is at the rate of 100° F. per mile. Cordier says 1° C. for every 25 metres, or 1° F. in 45 feet.

Another statement is that the increase in temperature of the earth's strata shows a mean average for the entire earth surface of 1° F. for every 56 ft. of depth.

Specific Heat.

M = weight of body. T = temperature of body. C = specific heat of body.
m = weight of cold water. t = temperature of cold water.
θ = temperature of water after body has been plunged into it.

$$C = \frac{m(\theta - t)}{M(T - \theta)}$$

PROPERTIES OF GASES, &c

(W. H. Booth.)

In the tables pages 196 to 199 are given many figures relative to the gases chiefly, which are of interest in questions of heat, combustion, and the gas engine. The figures are principally based on Berthelot's thermal determinations of the calorific capacity of the gramme molecule, the figure for which, if divided by the molecular weight, gives the heat generated per gramme of the substance. An attempt is made to give the correct values of the specific heat at high temperatures, with a view to the bearing of this property on the theory of the gas engine, and the possibly erroneous ideas as to the supposed effects of dissociation, which have been much overrated. The thermo-physical properties of carbon are more fully tabulated than has hitherto been attempted, with a view to explain the variations due to allotropism.

Heat and Combustion.

There are in practice only two elementary fuels, carbon and hydrogen. They generate heat by union with oxygen, and their compounds are also available as fuels.

Heat is measured in units. The British thermal unit B.Th.U. is the amount of heat necessary to raise 1 pound of water 1° F., and its mechanical equivalent is J = 778 pounds raised 1 foot in the latitude of Manchester; this last an unnecessary refinement in engineering.

The metrical or French calorie is the amount of heat necessary to raise 1 gramme of water 1° C. This is the 'petit calorie.' The great calorie is the heat necessary to raise 1 kilogram of water through 1° C. The mechanical equivalent is 427 kilograms raised 1 metre at the latitude of Paris; this latter refinement being unnecessary in engineering. The following table gives the ratios of English and French units:

1 Caloric = ·001 great calorie.	1 B.Th.U. = 1055 joules = 778 foot-pounds (until recently the accepted value was 772)
1 Great calorie = 3·968 B.Th.U.	
1 B.Th.U. = 0·252 great calorie.	1 Great calorie = 3087·3 foot-pounds.
1 Great calorie = 427 kilog. metres.	1 B.Th.U. = 107·6 kilog. metres.

Chemists use somewhat different terms and state calorific measurements in terms of the molecule. The gramme molecule of hydrogen is the unit employed. One gramme molecule of hydrogen, H_2, taken at 0° C. and 760 mm. of pressure of a mercury column, weighs 2 grammes and has a volume of 22·32 litres. The molecular weight of any other simple or compound gas is the weight which occupies the volume occupied by 2 grammes of hydrogen, that is 22·32 litres. The molecular specific heat of a gas is the heat of this volume in 'petit calories.' Then the molecular heat divided by the molecular weight will give the specific heat per unit weight or gramme; and the molecular heat divided by 22·32 will give the specific heat per unit of volume.

The specific heat of a gas is usually stated at constant pressure and at constant volume. In a perfect gas the ratio of these two is about 1·4 at ordinary temperatures. This is an erroneous way of putting it. The difference is really due to work done on the atmosphere in expanding to constant pressure. This work is invariable at 1·94 calories. The true ratio of specific heat at constant pressure or Cp to that at constant volume Cv, is thus properly stated, $Cp = Cv + 1·94$, or usually $= Cv + 2$. Thus, if 22·32 litres of gas are heated 1° C. from 0° C. they will perform work against a column of mercury 760 mm. high to the extent of 1·94 calories at all temperatures. A gas expands when heated 1° C. to an additional bulk $= \frac{1}{273}$ of the bulk occupied at 0° C. Hence the invariable quantity 1·94.

The specific heat of a gas increases with temperature. The number of calories generated by the combustion of a unit weight of a substance if divided by the specific heat of the products of combustion and by the total weight of such products, will give the nominal temperature. The 'theoretical' temperature of combustion is the nominal temperature found by using the specific heat at ordinary temperatures. These nominal temperatures are never attained. The ordinary specific heat of carbon dioxide is quadrupled at 4000° C., and the temperature that might theoretically reach 18000° C., in oxygen in a certain case would not go beyond 4500° C. or thereabouts.

The calorific capacity of fuel may be approximated by calculating the capacity of its constituents of carbon and hydrogen. This is absolutely accurate, subject to allowance for the heat of formation. Thus in the formation of some hydrocarbons, heat is evolved. When these hydrocarbons are burned, the heat which was produced in their original formation cannot be again produced, and the combustion is productive of so much less heat. Others, such, for example, as acetylene, absorb heat when formed, and this substance when burned gives out more heat than corresponds with its carbon and hydrogen. This is one reason for its brilliance, and accounts for its explosive tendency.

Combustion of Carbon.

Carbon exists only as a solid and is found in three forms or allotropic modifications : (*a*) the diamond ; (*b*) graphite ; (*c*) amorphous, as charcoal. The heat generated by the perfect combustion of each of these forms is peculiar to that form. Carbon exists in liquid form only in combination with other substances and does not vaporise except at 3600° C. The total heat of combustion of carbon is 11·646 calories per gramme from the state (*a*). Of this amount ·2783 calories disappear in converting the diamond to the amorphous state (*c*) ; 3·231 calories are absorbed in vaporising the carbon ; and 2·4533 calories are set free by its conversion into monoxide CO. 5·684 calories are then produced by the second oxidation of this CO into dioxide $=CO_2$. In practice the only available heat is that which is set free after vaporising the carbon, *i.e.* 8·137 calories. The following table gives these characteristics in brief, of converting 1 gramme of carbon.

	Calories.
1. Converting diamond to graphite	= ·041
2. „ graphite to amorphous	= ·237
3. „ diamond to amorphous (1)+(2)	= ·278
4. „ amorphous to monoxide CO	= 2·453
5. „ monoxide to dioxide	= 5·684
6. Vaporising amorphous carbon (5) − (4)	= 3·231
7. Total energy generated converting carbon vapour to dioxide (1)+(2)+(4)+(5)+(6)	= 11·646
8. Total available heat in practice (7) − (3) − (6)	= 8·137

The difference between (7) and (8) represents expenditure in unlocking the crystal form of the diamond (3) and in converting the carbon to gas (5). The latent heat of vaporisation of carbon is thus 3·231 or about half that of steam.

Hydrogen is known in three states, liquid, solid, and gaseous. The liquid and solid states are those of low temperature. All practical determinations start from the gaseous state. The following figures are found in the combustion of 1 gramme of hydrogen :

	Calories generated.
1. Converting hydrogen to water gas, H_2O,	29·15
2. „ „ „ liquid	34·50
3. „ „ „ solid	35·2

The ordinary available heat is that of (1) only; (2) being only partially secured when the products of combustion are cooled considerably below 100° C.

Stated per pound, carbon yields 14,500 British heat units, and hydrogen 52,000 to 62,100 according to the final temperature. The first oxidation of 1 lb. of carbon to monoxide yields barely 4,500 heat units : the further oxidation of the resulting carbonic oxide yielding fully 10,000 units.

The difference of the two oxidations is due to the rendering latent of about half the heat of the first oxidation in gasifying the solid carbon. The following equivalent units are useful:

1 Calorie per square metre	= 0·369 B.Th.U. per square foot.
1 B.Th.U. per square foot	= 2·713 calorie per square metre.
1 Calorie per kilogram	= 1·800 B.Th.U. per pound.
1 B.Th.U. per pound	= 0·556 calorie per kilogramme.

These calories are the great calories (p. 193).

For thermo-chemical tables of gases see pp. 196 199.

The temperature produced by combustion is largely dependent upon the weight of the resultant product. Thus 1 lb. of hydrogen when burned to water vapour will produce 52,380 heat units, which have to be divided among the 9 lbs. of water. The nominal temperature is 14,375° F. which, however, is based on the supposititious constancy of the specific heat; 1 lb. of carbon, however, which only generates about 14,500 heat units, produces only $3\frac{2}{3}$ lbs. of gas, and the nominal resulting temperature is 18,457. These are for combustion in oxygen. With air the additional weight of nitrogen still further reduces the nominal temperatures to about 5,000° in each case.

The percentage of each constituent of a mixed product must be multiplied by the specific heat in order to find the true valency of that product in the calculation of temperature. To find the mean specific heat of a mixture of gases, the weight of each gas is to be multiplied by its specific heat. The products are to be added together and divided by the sum of the weights of all the gases. The result is the mean specific heat. Then the temperature of combustion is found by dividing the total heat of combustion of the combustible gases by the weight of products and by the mean specific heat.

Similarly the calorific value of a mixed gas is found by multiplying the weight of each gas by its calorific value per pound, adding the products together and dividing by the total weight. The result is the thermal value per pound of the mixed gas.

[NOTE.—Gases expand by heat to the extent of $\frac{1}{273}$ of their bulk at 0° C. for each degree Centigrade, or $\frac{1}{491{\cdot}4}$ of their bulk at 32° F. for each degree Fahr.

✡ The specific heat of gases varies with the temperature, being more for higher temperatures. At the absolute zero the values of the molecular heat of all gases seem to converge at 6·5 for constant pressure values. Lechatelier therefore gives a formula for specific heat $Cp = 6{\cdot}5 + \alpha T$, where T is the absolute temperature Centigrade and α is a coefficient greater according to the complexity of the molecule. For values of α see table. This has an important bearing on the theory of the gas engine.]

[T = Temperature Centigrade.]

The superficial expansion is twice the linear, and the cubical expansion three times the linear. The coefficient of expansion of an alloy is equal to the mean coefficients of expansion of the volumes of the metals composing it.

If a bar is *increased* in length from l to L by an *increase* of temperature of $t°$, then

$$L = l(1 + at°).$$

If a bar is *decreased* in length from L to l by a *decrease* of temperature $t°$, then

$$l = \frac{L}{1 + at°}.$$

Change in Density of a Body by Change in Heat.

If *decrease* in density be from d to d' by an *increase* of temperature of $t°$, then

$$d' = \frac{d}{1 + ct°}.$$

If *increase* in density be from d' to d by a *decrease* of temperature of $t°$, then

$$d = d'(1 + \alpha t°).$$

1. Solids have a much smaller coefficient of expansion than liquids.
2. The coefficient of expansion of liquids increases with the temperature.
3. The coefficient of expansion of a liquid which only preserves its state under very great pressure is probably very great.

Expansion of Air by Heat.

Dry air expands or contracts uniformly ·002039 its volume per F.° difference under *constant pressure.*

If the *volume is constant* and the pressure varies, then the coefficient per F.° is ·002036.

Flash Temperatures.

Dr. H. Holm finds that the temperature at which substances in contact with atmospheric air at ordinary pressures will catch fire are, among others :—Lighting gas, 600°C ; benzine, 415°C. ; petroleum, 380°C. ; gas oil, 350°C. ; machine oil, 380°C. ; coal tar, 500°C. ; tar oil, 580°C. ; and benzol, 520°C. These temperatures are greatly influenced by the presence of other substances, which act as catalysers. This is especially the case with hydrogen, methane, and ethane, not ethylene or acetylene. Among solids it is the substances with the biggest molecules which most readily burst into flame. As a broad rule, the nearer a substance is to a gaseous condition, the higher the temperature to which it must be exposed before it will kindle : but this depends also on the chemical constitution.

See also page 185.

SOUND.

Velocity of Sound through Air.

v = velocity in feet per second.
t = temperature of the air, Fahr. scale.
D = distance in feet the sound travels in the time, T.

$$v = 1089{\cdot}42\sqrt{1 + 0{\cdot}00208\,(t - 32)}.$$

The velocity of sound in water is about four times that in air.

$$D = 1089{\cdot}42T\sqrt{1 + {\cdot}00208\,(t - 32)},$$

$$T = \frac{D}{v}.$$

Example.—A ship at sea was seen to fire a cannon, and 6·5 seconds afterwards the report was heard ; the temperature of the air was 60°. Required, the distance to the ship.

$$D = 1089{\cdot}42 \times 6{\cdot}5\sqrt{1 + {\cdot}00208\,(60° - 32)} = 7{,}300 \text{ feet, or } 1{\cdot}38 \text{ mile.}$$

The intensity of sound decreases as the square of the distance.

The intensity of sound increases as the square of the amplitude of the vibrations of the sonorous body.

The intensity of sound depends on the density of the air in the place at which it is produced.

The intensity of sound is greater in the direction of the wind than in the contrary direction.

Distances at which Sounds can be Heard.

Descriptions of Sounds.	Audible at a Distance of	
	Feet.	Miles.
A powerful human voice in the open air, no wind	460	0·087
Report of a musket	16,000	3·02
Drum	10,500	2
Music, strong brass band	15,840	3
Cannonading, very strong	575,000	90
In a barely observable breeze a strong human voice with the wind can be heard	15,840	3

Velocity of Sound through Solid Substances in Feet per Second.

Metals.				Woods.			
Lead	4,000	Copper	11,700	Pine	10,900	Elm	13,500
Gold	5,700	Steel wire	15,500	Oak	12,600	Fir	15,200
Silver	8,550	Iron	16,800	Ash	13,300	Aspen	16,700

Speaking-Tubes.

The greatest distance at which a sound signal, strongly and clearly given, can be heard through a straight line of tube, without branches, is about 1,500 ft., and cannot exceed 1,650 ft.

The best sizes for speaking-tubes are 1·2 in. for distances below, and 2·1 ins. for those above 650 ft., in single lines; and for branched systems up to 160 ft., ·80 in.; 160 to 500 ft., 1 in.; 500 to 1,000 ft., 1·3 in.; above 1,000 ft., 2·1 ins. Below 1·2 in. the frictional resistance to the sound waves is too great, and above 2·1 ins. it is beyond the power of the average human voice to set the enclosed air in vibration with the necessary intensity.

The greater the diameter of the tube the louder must the voice and the clearness of the articulation of the speaker be.

Vowel sounds are more readily heard than consonants, and longer rather than short accented ones.

Sheet zinc, on account of its low elasticity, is the best material for tubes, although in most cases galvanised iron may be preferred on account of the readiness with which it transmits knocker signals.

Screwed collars are preferable to flanges for joining the tubes.

The tubes must be as smooth as possible inside, and sudden changes of section are to be avoided.

Although the best method of isolating the tubes is to inclose them in earth or masonry, it will be more convenient in most cases to use earthenware pipes as casings suspended from the roof of the levels, which need only be solidly clamped at the stations.

Changes in the direction of the line and branch connections are best made by curves of not less than 16 ft. radius. When there are many branches, these should be only signalling points, the others being all receiving stations. If, however, a line is required for giving signals from both ends, it may be utilised for intermediate points by short receiving branches, about 16 ft. long, connected with the main line by proper curves. The number of these branches should not, however, be more than two for a 1·6-in. tube of 1,000 ft., or three for one of 2·1 ins. and 1,300 ft. In cases of greater complexity it is better to establish repeating stations at intervals of about 650 ft.

The best call signals for great distances are made by striking the side of the tube; but a bugle may be used, if it is pressed close to the mouthpiece. Whistles are inaudible except at short distances.

The oval or elliptical mouthpieces commonly used on short lines are quite useless. The most convenient arrangement is to make the end of the tube slightly conical, widened to about 1·5 in. in diameter, and cover it with a flat wooden ring, like a telephone, which can be used either for speaking or hearing with the minimum loss of sound.

OPTICS.

LIGHT.

Decomposition of Light in the Spectrum.

Colours.	Maximum Ray.	Combination of Colours.		
		Primary.	*Secondary.*	*Tertiary.*
Violet	Chemical			
Indigo		Blue		
Blue	Electrical	Yellow	Green	
Green				Dark Green
Yellow	Light	Blue	Purple	
Orange		Red		Brown
Red	Heat	Yellow	Orange	
		Red		

All the colours of the spectrum mixed together make white, which is proved by the decomposition of white light, which makes the seven colours.

Velocity of Light.

Velocity of light $= 3 \cdot 004 \times 10^{10}$ cms. per sec. Mean wave length $= 5 \cdot 3 \times 10^{-5}$ cms.

The velocity of light through the atmosphere is 186,330 miles per second (*Newcomb*). The velocity of light through transparent bodies is not known, but probably varies inversely as the square root of the specific gravity of the transparent substance.

Light passes from the sun to the earth ($1{\cdot}487 \times 10^{13}$ cms. = 92,390,000 miles [*Everett*]) in eight minutes, at which velocity light can pass around the earth in one-eighth of a second.

To find the Focal Length of a Convex Mirror.

Use as object an opaque screen, with a hole and pin-point, and painted white, or covered with white paper.

Set up on the bench, in line, say, with the left edge of the hole, the convex mirror and an auxiliary biconvex lens of short focal length (6 ins. or so), and adjust the lens so that the image of the hole and pin-point is formed side by side with the object. The centre of the mirror is now at the point at which the image would be formed by the lens alone ; this position may either be calculated or found (after noting the position of the mirror and then removing it) by means of a screen. Thus the radius is easily measured.

If the focal length of the mirror be greater than f, that of the lens, the simplest way of adjusting is to put the lens as close as possible to the mirror, put the object at principal focus of lens, and move the object back until the image is formed as above.

If, however, the focal length be less, we can be sure of finding the position by putting the mirror at a distance of 4 f from the object, and the lens at 2 f, and moving the lens back until the desired position is reached.

To find the Focal Length of a Concave Lens.

Use an object like the one mentioned above, an auxiliary convex lens (say, 6 ins. focal length) to produce a convergent beam, and an auxiliary plane mirror, placed beyond the concave lens.

Adjust until the image is formed side by side with the object, as before ; then the rays must be emerging parallel to one another from the concave lens, and hence the convergent beam from the convex lens will (when the concave lens and mirror are removed) form an image at the principal focus of the concave lens. A direct measure can thus be made of the focal length.

(*E. Budden.*)

Luminous Energy.

In a series of lectures on ' Flame,' at the Royal Institution, Sir James Dewar illustrated in a striking form a fact which has long occupied the attention of scientists in relation to the energy expended in the production of light. The following figures show how utterly imperfect are the various lighting devices now employed on a basis of scientific efficiency :—

Lighting Device.	Percentage of Light.	Non-Luminous Energy.
Candle	2	98
Oil	2	98
Coal Gas	2	98
Incandescent lamp	3	97
Arc lamp	10	90
Magnesium lamp	15	85
Cuban firefly	99	1

Specific Gravity.

The specific gravity of any substance in the C.G S. system is its weight in grammes per cubic centimetre.

The relative specific gravity of a body is its weight as compared with that of an equal bulk of some other body which is adopted as a standard of comparison. For other substances than air and gases generally, pure water is the usual standard; and since the weight of a given bulk of water varies somewhat with its temperature, and also with the state of the air, the former is assumed to be 62° F., and the latter at 30 ins. at sea-level. On the Continent of Europe water at its greatest density, or at a temperature of 4° C., = 39·2° F., is taken as the standard. But where extreme scientific accuracy is not aimed at all these considerations may be neglected, and any clear fresh water, at any ordinary temperature—say from 60° to 80°—may be used. From 4° C. water expands regularly as the temperature rises; so that 1,000 parts at 0° C. become at 0° = 1,000·00, at 4° = 999·88, at 10° = 1,000·14, at 20° = 1,001·67, at 30° = 1,004·21, at 40° = 1,007·61, at 50° = 1,011·93, at 60° = 1,016·86, at 70° = 1,022·43, at 80° = 1,028·73, at 90° = 1,035·58, at 100° = 1,043·03. Pure water weighs 62·288 lbs. avoir. per cubic foot (*International Bureau of Standards, Paris*, 1921). The following shows the principal weights, etc., of water.

WATER.

Detail.	Fresh.	Salt.
Greatest density at	39·2° F.	Freezing-point
1 cubic foot at 39·2° F. weighs	62·288 lbs.	64 lbs.
1 cubic inch „ „	·036047 lb.	·037037 lb.
1 cubic foot „ equals	6·2288 gallons	6·3 gallons
1 gallon at 62° F. weighs	10 lbs.	10·3 lbs.
1 ton equals	35·962 cub. ft.	35 cub. ft.
1 ton contains	224 gallons	217 gallons
Freezes at	32° F.	27° F.

See also Section XXIV., HYDRAULICS, p. 1125.

To find Specific Gravity.

Solids.

W = weight of a body in the air.
W = weight of the body (heavier than water) immersed in water.
S = specific gravity of the body.
Then

$$W - W : W = 1 : S. \quad S = \frac{W}{W - W}.$$

When the body is lighter than water, annex to it a heavier body that is able to sink the lighter one.

S = specific gravity of the heavier, annexed body.
s = specific gravity of the lighter body.
W = weight of the two bodies in air.
W = weight of the two bodies in water.
w = weight of the heavier body in air.
w = weight of the lighter body in air.

$$s = \frac{w}{W - W - \frac{w}{S}},$$

A simple way to obtain the specific gravity of a wood is to form it into a parallel rod, and place it vertically in water; then, when in equilibrium, the immersed end is to the whole rod as the specific gravity is to 1.

Liquids.

Measure the weight of a stoppered-glass bottle; then fill the same with distilled water and weigh it again; the difference between the two measurements gives the weight of the distilled water. Then completely empty out the water and refill the bottle with the liquid whose specific gravity is required, and again weigh; this weight less the weight of the bottle gives the weight of the liquid; this weight divided by the weight of the water gives the specific gravity of the liquid.

In practice it is convenient to employ a bottle (called a specific gravity bottle) that holds exactly 10 grammes of distilled water at 4° C., because, when such a bottle is filled with the liquid under trial the weight in centigrammes of the liquid taken at 0° C. represents the specific gravity at once, without calculation. For convenience a counterpoise of brass is adjusted to the weight of the bottle.

Gases.

Measure in the same way as liquids, taking Air as the standard. A large and very light, i.e. thin, glass vessel must be used for the purpose, otherwise the weight of the glass will swamp as it were, the weight of the enclosed gas, and accurate results cannot be obtained. Certain corrections have to be made in practice, for great accuracy.

To find the Specific Gravity of a mixture of given volumes of any number of fluids whose specific gravities are given.

If V_1, V_2, V_3, . . . V_n be the volumes of the fluids whose respective specific gravities are s_1, s_2, s_3, . . . s_n, and S the specific gravity of the mixture, then

$$S = \frac{V_1 s_1 + V_2 s_2 + V_3 s_3 + \ldots V_n s_n}{V_1 + V_2 + V_3 + \ldots V_n}.$$

To find the Specific Gravity of a mixture of given weights of any number of fluids whose specific gravities are given.

If W_1, W_2, W_3, . . . W_n be the weights of the fluids whose respective specific gravities are s_1, s_2, s_3, . . . s_n, and S the specific gravity of the mixture, then

$$S = \frac{W_1 + W_2 + W_3 + \ldots W_n}{\frac{W_1}{s_1} + \frac{W_2}{s_2} + \frac{W_3}{s_3} + \ldots \frac{W_n}{s_n}}$$

To Discover the Adulteration in Metals, or to find the Proportions of Two Ingredients in a Compound.

$$w = \frac{W - s\,(W - W)}{1 - \frac{s}{S}}.$$

EXAMPLE.—A metal compounded of silver and gold weighs, W=6 pounds in the air, and in water, W=5·636 pounds. Required the proportions of silver and gold.

S=19·36 specific gravity of gold. s=10·51 specific gravity of silver.

$$\text{Weight } w = \frac{6 - 10{\cdot}51(6 - 5{\cdot}636)}{1 - \frac{10{\cdot}51}{19{\cdot}36}} = 4{\cdot}755 \text{ pounds of gold.}$$

and 1·245 pounds of silver.

SPECIFIC GRAVITIES OF WOODS.

The specific gravity or weight per cubic inch or cubic foot of woods can never be expressed by a fixed value. Wood varies in the same tree from the root to the branches, becoming lighter upwards, and again varies from the lower branches to the top in the reverse way, *i.e.* it becomes heavier upwards. It also varies from within outwards, and also varies according to the time of year, starch being accumulated at one season and used up at another. No two pieces of wood can be found of the same specific gravity except by accident, or by taking two small pieces from the same annual ring, which would rarely occur in practice. Hence it is misleading to work out specific gravities of woods to several places of decimals. Moreover, wood is hygroscopic, and however dry a specimen may be, a different result will be obtained with every movement of the barometer. The term 'dry weight' is merely an expression of convenience, and most of the figures given in the foregoing table have been calculated from specimens which have been kept in a dry room at ordinary temperatures, and which have ceased to lose weight. Wood dried by artificial means at high temperatures gains weight by absorbing moisture, this absorption taking place from the moment the wood is withdrawn from the desiccator.

Drying and Seasoning of Woods.

There is no difference between 'drying' and 'seasoning,' and the terms may be regarded as synonymous. Too rapid drying may be injurious to a wood, and hence seasoning has come to be regarded as something different from drying, but it is only so in certain cases, and is disputed even in these. Some foresters maintain that a few rings of wood nearest the heart pass from the condition of sapwood into that of heartwood during seasoning, and that therefore the amount of useable timber is increased thereby. (*H. Stone.*)

Specific Gravities of Elastic Fluids.

1 cubic foot of dry atmospheric air at 62° F. and at normal pressure weighs 532·5 troy grains. Its assumed gravity of 1 is the unit for elastic fluids.

Fluid	Specific Gravity Compared with Air.	Fluid.	Specific Gravity Compared with Air.
Atmospheric air	1	Sulphuretted hydrogen	1·17
Ammonia	·589	Sulphurous acid	2·21
Carbonic anhydride	1·52	Steam, 212°	·4883
„ oxide	·972	Smoke of bituminous coal	·102

SPECIFICATION OF SHEET METALS.

When specifying for sheet metals, care should be taken that the nature of the gauge is stated i.e. whether it is S.W.G., B.W.G., or Trade Gauge. In the case of 'Sheet Zinc,' for example, the Trade Gauge No. 20 is ·063 in. (see above, and Index, 'Sheet Zinc Trade Gauge'), but this if expressed in S.W.G. is 0·36 in. (see Index, 'Standard Wire Gauge').

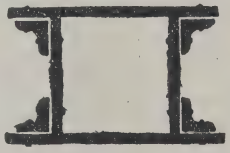
HENDERSON & GLASS,

Steel and Iron Merchants, LIVERPOOL.

Extensive and assorted Stocks of every description and section of Material for Engineers, Shipbuilders, Ironfounders, Contractors, &c., in Iron and Siemens-Martin Steel; also

ROLLED STEEL GIRDERS AND JOISTS.

All sizes from 3 to 20 inches deep and up to 40 feet lengths.



Ship, Boiler, Flitch and Chequered Plates, Channels, Round, Square, Flat Bars, Angles, &c.

COMPOSITE AND BUILT GIRDERS.

QUOTATIONS AND SECTION SHEETS ON APPLICATION.

Telegraphic Address—
'VULCAN,'
LIVERPOOL.

Telephone Numbers—
443, 791 and 3711 Central.

SHIPMENT ORDERS PROMPTLY EXECUTED. CORRESPONDENCE SOLICITED.

Offices and Warehouses:

18, 20, & 22 VULCAN STREET, LIVERPOOL.

List of Steel Joists and Channels in Stock, see following page.

F. 224

Telegraphic Address—'VULCAN,' LIVERPOOL. **TELEPHONE Nos. 443, 791, & 3711 CENTRAL.**

HENDERSON & GLASS,

LIVERPOOL,

HAVE IN STOCK TO-DAY THE UNDERNOTED

ROLLED STEEL JOISTS AND GIRDERS.

DIMENSIONS, WEIGHTS PER FOOT, AND SAFE DISTRIBUTED LOADS OF **JOISTS,** IN STOCK, READY FOR IMMEDIATE DELIVERY.

Pipes 2-in. bore in 6 ft. 3 ins. lengths; 3-in. bore to 9 ins., 9 ft. 4 ins. lengths; 9-in. bore to 48 ins., 12 ft. 4 ins. lengths.

The pipes are vertically cast in dry sand, socket down, and are tested to a pressure of 500 feet head (216 lbs. per sq. in.) of water; the fittings are tested to the same pressure. *(The Staveley Coal and Iron Co.)*

If the external diameter is given, subtract figure in black type at bottom of column; for example, the weight per lineal foot of a copper tube 2 inches external diameter, 12 S.W.G., is 2·65 − 0·26 = 2·39 *lbs.* The weights are calculated from 12 samples of tubes made from tough copper (specific gravity at 60° F. 8·8917, or ·3209 lb. per cubic inch). Brazed copper tubes weigh more than seamless; but an exact multiple cannot be given. Mandril-drawn brazed tubes weigh the same as seamless tubes. In practice a slight deviation from the above theoretical weights must be expected. To ascertain the weight of a seamless tube of other metal, multiply the weight of a similar copper tube by ·9626 for brass (70 and 30 alloy), by ·86 for wrought iron, by ·81 for cast iron, or by 1·28 for lead. (*The Broughton Copper Co., Ltd.*)

Weight of Seamless Brass Tubes.
(Containing 70 % of copper.)

The figures in italics show the difference in percentage of weight of brass tubes made to the B.W.G. and the S.W.G., the latter being taken at 100.

The above weights, multiplied by ·994, give the weight of a brass tube 2 and 1 alloy.

These weights are calculated from the specific gravity of 16 samples of tubes, from various makers, each of the samples being 1 foot long × $1\frac{3}{8}$ inch external diameter × 14 B.W.G., which was found to be 8·558, or ·3089 lb. per cubic inch, for the alloy of 70 and 30, and 8·508 specific gravity, or ·3071 lb. per cubic inch, for the alloy of 2 and 1 at a temperature of 60° F.

To ascertain the weight of a seamless tube of copper, multiply the weight of a similar brass tube by 1·0388.

BRITISH STANDARD SPECIFICATION FOR CAST-IRON PIPES AND SPECIAL CASTINGS FOR WATER GAS AND SEWAGE.*

(No. 78–1917).

(*Abstract.*)

2. The metal used for casting the pipes shall be pig iron alone, or pig iron and scrap, and shall be remelted in the cupola or air furnace. The pig iron shall be best tough grey foundry pig iron, and the scrap shall be clean, unburnt and of good quality. There shall be no admixture of cinder iron or any material calculated to render the metal inferior in quality, and the resulting casting shall not be white or vitreous on fracture.

7. The tensile breaking strength of the metal shall be not less than 9½ tons per square inch.

11. The straight pipes shall be cast vertically, in dry sand moulds formed from turned iron patterns and in accurately faced and truly jointed boxes, and without the use of core nails, chaplets, or thickness pieces, or any substitute therefor. They shall be cast with a sufficient head of metal to ensure soundness, which head shall be afterwards cut off in a lathe and the finished pipe left the length and shape required. All straight spigot and socket pipes shall be cast socket downwards.

22. The straight pipes shall, before being coated, respectively withstand the following hydraulic test pressures without showing any leakage, sweating, or other defect of any kind :—

	Gas.	Water.		
	Class A.	Class B.	Class C.	Class D.
Test pressure in feet head . .	200	400	600	800

While under the test pressure each pipe shall be smartly struck with a suitable hand hammer weighing not less than one and a half pounds.

TENSILE STRENGTH OF MATERIALS — STRENGTH OF WIRE, CHAINS, AND ROPES—LATERAL STRENGTH OF MATERIALS—ADMIRALTY TESTS OF STEEL AND IRON —LLOYD'S TESTS—BUREAU VERITAS TESTS—INDIAN STATE RAILWAY TESTS—STRENGTH OF TUBES, RINGS AND CHAINS.

STRENGTH OF MATERIALS.

This Table shows the weight a column can bear with *safety* when the weight presses through the length of the column. The tabular number is the weight in pounds or tons per square inch on the transverse section of a column of a length less than twelve times its smallest thickness.

RESISTANCE TO COMPRESSION.

FIG. 381.

Kind of Material.	Lbs.	Tons.
Oak of good quality	432	·1885
„ common	280	·125
Spruce, red (Sapin rouge)	540	·241
„ white (Sapin blanc)	140	·6256
Iron, wrought	14,400	6·43
„ cast	28,750	12·85
Basalt	2,875	1·285
Granite, hard	1,000	·446
„ common	575	·256

High-Class Engineering Alloys

'DELTA' BRAND

(REGISTERED TRADE MARK)

BRONZE, BRASS, YELLOW METAL, NAVAL BRASS, COPPER, &c.,

Castings, Forgings, Stampings, Pressings, Sheets, Tubes, Wire, Rods of any Section,

FOR

Marine Engineering, Shipbuilding, Mining, Sanitary and Electrical Work, Chemical Factories, Gas and Water Works, Gunpowder Magazines, etc.

Strongest Malleable Bronzes;
Acid-proof and other Corrosion-resisting Alloys;
Improved Bearing Metals;
White Anti-friction Metals, etc.

Supplied to British Admiralty, War Office, and other Tests and Specifications.

For prices and particulars please apply to:

The Delta Metal Company, Ltd.

EAST GREENWICH, LONDON, S.E. 10
(or Dartmouth Street, BIRMINGHAM).

On the lists of the Admiralty, War Office, Ministry of Munitions, Air Ministry, India Office, Post Office, Crown Agents for the Colonies, Principal Foreign Governments, Railway and Steamship Companies, etc.

When ordering, kindly specify the exact Brand or number of metal or material required. [SEE OTHER SIDE.

Tensile Strength of Metals at Different Temperatures.

TENSILE STRENGTH OF IRON, STEEL, AND CAST IRON AT HIGH AND LOW TEMPERATURES.

The tensile strength of wrought iron or steel appears to be a minimum at about 70° F., and increases as the temperature is changed, becoming 20 per cent. greater at about 500° F. There are indications of a brittle region at the temperature of steam at 5 to 10 lbs. pressure. Iron at low temperatures, while increasing in strength, retains its ductility.

The tensile strength of cast iron begins to decrease at as low a temperature as 200° F., and at a dull red heat, say about 1,000° F., its strength is reduced by one-third; at 1,240° F. it is reduced to zero.

THE EFFECT OF SUPERHEATED STEAM TEMPERATURES ON STEEL.

Based upon Experiments made in the Brown-Firth Research Laboratories, Sheffield

(*Contributed by W. H. Hatfield, D.Met.*)

Steam at 400 lbs. per sq. in. pressure and 350° of superheat probably represents the highest temperature at which steam is likely to be used. This corresponds to about 845° F. or 452° C. As the testing temperature increases from atmospheric to about 500° C. most types of steel show first an increase of strength, then a decrease. A mild carbon steel which at ordinary temperatures gave 27·2 tons per sq. in. maximum stress with 38 per cent. elongation gave at 200° C. 30 tons per sq. in. and 27 per cent. elongation, at 300° C. 32·3 tons per sq. in. with 23 per cent. elongation, but at 400° C. fell to 25·1 tons per sq. in. maximum stress with 37·6 per cent. elongation. At 550° C. the maximum stress was only 16·8 tons per sq. in. Carbon steel of higher carbon content shows a similar order of changes, but there is in some cases a slight decrease in strength at about 100° C. before the increase takes place. The temperatures at which

the steel has its maximum strength varies with the steel, a higher carbon generally bringing the maximum at a lower temperature. A 52-ton carbon steel gave 50 tons per sq. in. at 100° C., 53 tons per sq. in. at 200° C., 58 tons at 310° C., 48·5 tons per sq. in. at 420° C., and so on. A nickel chrome steel, which gave 37 tons per sq. in. and 30 per cent. elongation at ordinary temperatures, gave only 32·4 tons per sq. in. at 200° C.; 29 per cent. elongation followed by an increase of strength to 34·2 tons per sq. in., with 33 per cent. elongation at 410° C. Beyond this temperature the strength fell off rapidly.

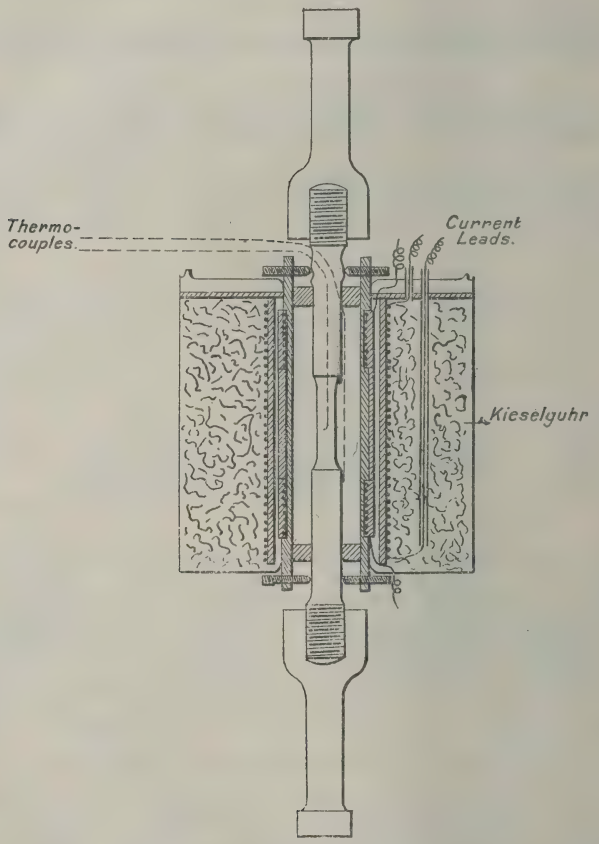

FIG. 381A.

Tests in Firth's stainless steel, which had a strength of 55·0 tons per sq. in. and 21 per cent. elongation at ordinary temperature, retained a strength of 45·0 tons per sq. in. with 22 per cent. elongation at 410° C., after falling slightly below this strength at 300° C. A specimen of high speed tool steel in an annealed condition showed a gradual reduction in strength as the temperature increased. The values were 50 tons per sq. in., and 21·6 per cent. elongation at ordinary temperature, and 36·4 tons per sq. in. 19·2 per cent. elongation at 460° C. This stainless steel and high speed steel retain their strength to a considerable degree up to 600° C.

A further test on nickel steel showed a decrease of strength from 48·6 tons per sq. in. to 39·2 tons per sq. in. at 250° C., followed by an increase to 43 tons per sq. in. at 350° C., and a further decrease to 32·7 tons per sq. in. at 500° C. The elongations per cent. at these temperatures were, ordinary 23·2 per cent. ; 250° C., 21 per cent. ; 350° C., 19 per cent. ; 500° C., 2¼ per cent.

For use in steam turbines, the above properties require careful consideration, since, of course, the design and strength of the parts should be based on the properties of the material at the actual working temperature.

For making the above determinations, a special small electric furnace (fig. 381A) was constructed and used for heating the specimens. An iron tube about 7¼ ins. long and 1½ ins. internal diameter and $\frac{3}{16}$ in. thick was turned down, except about 1½ in. length at each end, to about $\frac{3}{7}$ in. thickness. The main heating coil was a spiral of nichrome wire wrapped on a silica tube of 2¼ ins. diameter and fixed concentrically with the iron tube. Auxiliary heating coils were added at each end of the turned portion of the central tube, being separated from the latter by a layer of mica, and covered with a coating of refractory cement. A cylindrical metal box surrounded the whole, the space being filled with refractory material (kieselguhr). The object of the metal tube was to equalise the temperatures over the central portion of the furnace, and the end heating coils were added to compensate for the heat lost by radiation at the ends of the furnace. The tests were carried out in the Olsen testing machine. The test piece was 10 ins. long, having the test portion 1½ in. parallel, by 357 mils diameter (i.e. $\frac{1}{10}$ sq. in. cross section). This was located axially in the furnace by three set screws carried at each end of the iron tube. The screwed ends of the test piece were connected to the shackles of the machine by special gluts of 25 per cent. nickel steel, which has fairly low heat-conducting properties. This was found to be necessary in order to prevent the shackles and attachments of the machine from heating up unduly. The weight of the furnace was carried by the test piece itself from its upper end, a groove being turned on the test piece so that the upper set screws could be screwed tightly on it. The lower set screws were turned so as to only bear lightly on the test piece, thus permitting the lower portion of the latter to pass through easily, when elongation and fracture took place during the test. The heating coils, in series with a suitable resistance, were connecting across the 200-volt. A.C. supply mains. The temperature was measured by means of two thermo-electric couples, which had been previously calibrated. One was placed with the junction at the centre of the parallel portion of the test piece, and the other just above the end of the 'radius' so as to detect any variation in the temperature. The couples were tied in position on the test piece by fine wire previous to inserting in the furnace. To prevent any air current passing through the furnace the ends of the tube were packed with asbestos packing.

Strength of Steel at very High Temperatures.

(W. H. Hatfield.)

It frequently happens that engine parts have to work at still higher temperatures than those corresponding to superheated steam. Valves, pistons, and other parts of internal combustion engines, boiler flues, etc., are examples of such parts.

It is generally found that as the temperature rises above 500° C. the mechanical strength falls off fairly rapidly, whatever the composition of the steel. A mild steel of ·14 per cent. carbon content showed a strength of 9 tons per sq. in. at 640° C. and a strength of only 2·5 tons per sq. in. at 850° C. Under such conditions, however, the strength exhibited depends largely on the speed of deformation. A relatively small load will frequently cause a gradual breakdown of the material if the load is maintained. The order of strengths exhibited at 850° C. is somewhat as follows :— Mild carbon steel, higher carbon steel, nickel chrome steel, Firth's stainless steel, tungsten high-speed steel. A sample of the latter gave a strength of 11 tons per sq. in. when tested at 850° C. when suitably hardened and tempered.

It might be of interest to note that a quality of high speed steel having the condition of hardness in which it is employed as a tool (and in which it retains its cutting properties while working at a red-heat) had a strength of 78 tons per sq. in. at a temperature of 625° C.

Tensile Strength of Copper at Different Temperatures.

Temperature, °F . . .	122°	212°	302°	482°	545°	602°	801°	912°	1010°
Lbs. per square inch . .	33,100	32,200	30,900	27,000	25,400	22,300	18,900	14,800	11,100

Copper may suffer considerable loss in strength when exposed for a long period to variable temperatures, even if as low as 400° F. Le Chatelier found that at this temperature the ultimate tenacity of good copper thoroughly annealed is not more than 10 tons per square inch, while this figure cannot be depended on in the case of brazed pipes, as the metal is often seriously injured in the neighbourhood of the joint. Hard copper suffers more than soft annealed copper

from the effects of heat. Le Chatelier's test showed that with a hard copper having a tenacity of 31·5 tons per sq. in., at 60° F. the strength was reduced to 11·4 tons after being exposed to a temperature of 482° F. for 30 minutes. Under the same conditions the tenacity of soft copper was reduced from 15·9 to 10·4 tons per sq. in. Prof. Roberts-Austen showed that minute quantities of impurities in copper seriously affect its tenacity. The presence of one-tenth of 1 per cent. of bismuth reduced the breaking load of a sample from 8 tons per sq. in. at 64° F. to 1·7 tons at 390° F. (*Philip Dawson, M.I.C.E.*)

TENSILE STRENGTH OF DELTA BRONZE NO. IV. AT DIFFERENT TEMPERATURES.

Delta Bronze, No. IV. Cast, tested at increased temperatures by Professor W. C. Unwin had lost :—

At 410° F.	. . . .	5·9	per cent.	of its original strength
„ 506° F.	. . . .	17·6	„	„ „
„ 590° F.	. . . .	33·0	„	„ „

that is to say, at a temperature as high as 590° F. it still retained two-thirds of its original strength.

TENSILE STRENGTH OF GUN-METAL AT DIFFERENT TEMPERATURES.

Gun-metal (9 of copper and 1 of tin) becomes perceptibly softer at 400° F., and at 550° F. its tenacity is reduced one-half; at 1380° F. (750° C.) it almost reaches zero. This is no doubt due to a large extent to the tin element, the melting-point of which is 446° F. But it is not altogether the melting-point of the individual constituents which appear to influence the matter. Copper, for instance (see p. 251), has a high melting-point (1929° F.), but its strength is seriously affected by prolonged exposure to a temperature as low as 400° F. Superheated steam will affect gun-metal (and other alloys) by chemical action, apart from the question of temperature.

REINFORCED SHEET LEAD.

A reinforcement of lead with perforated iron sheet has been found to increase the elastic limit four- to five-fold, and the tensile strength from two- to three-fold, the variations being due to differences in gauge of wire and mesh used. Lateral extensions of 20 per cent. and elongation of 20 per cent. have been obtained. Sheets 4 ft. 6 ins. by 5 ft. 6 ins. have been made. These reinforced sheets may be bent or shaped almost at will, as the lead does not fracture when bent. The sheets may be cut and joints burned together as in ordinary sheet lead. A pipe, 8 ins. in diameter, made up of reinforced lead 0·2 in. thick, when tested for strength, resisted pressures up to 85 lbs. per sq. in.

Stress due to Temperature.

A change of temperature = 16° C. (29° F.) for cast iron, and of 6½° C. (11·7° F.) for wrought iron, will produce 1 ton stress per square inch of section. For 45° C. (81° F.) wrought iron varies $\frac{1}{1800}$ of its length; this will produce 7 tons stress per square inch of section.

Corrosion of Metals.*

RELATIVE CORROSION OF SOFT STEEL, WROUGHT IRON, AND NICKEL STEEL, TAKING WROUGHT IRON AS A STANDARD.

HOLDING POWER OF GLUE.

Wood.	Pounds per Square Inch across the Grain End to End.	Pounds per Square Inch with the Grain.
Beech	2,133	1,095
Elm	1,436	1,124
Oak	1,735	568
White wood	3,149	341
Maple	1,422	896

Some elaborate tests carried out in Germany proved that joints made with ordinary joiners' glue are strongest when the glue is dissolved in 150 per cent. of water and applied to wood heated to 104° Fah. The joint was dried under a pressure of 284 lbs. per square inch for twenty-four hours, and had a breaking strength of 984 lbs. per square inch. Increases in the proportion of water or the temperature reduced the strength of the joint.

Breaking Stresses of Wire and Wire Ropes.

Particulars of ropes with higher breaking stress and larger sizes can be furnished on application to the makers.

RESISTANCE TO TORSIONAL RUPTURE.

RELATIVE POWER OF RESISTANCE TO TORSIONAL RUPTURE BY SHOCK OF VARIOUS WOODS.

White pine	1·00	Yellow pine	3·87
Spruce	1·50	Black walnut	3·95
Red cedar	1·61	Locust	5·80
Spanish mahogany	1·65	Oak	6·60
Ash	2·25	Hickory	6·90
Chestnut	2·40		

In a report issued by the Forest Service of the United States Department of Agriculture, it is stated that a wooden beam can take twice as much deflection under impact as under ordinary rates of loading without showing loss of elasticity. Increased rate of loading is accompanied by an increase in strength.

STIFFNESS.

RELATIVE STIFFNESS OF WOODS.

(Ratio of twisting moment to total angle of torsion.)

White pine	1·00	Red cedar	4·00
Yellow pine, sap	2·25	Spanish mahogany	3·00
,, ,, heart	2·25	Oak	2·53
Spruce	0·67	Hickory	4·1
Ash	1·87	Locust	5·50
Black walnut	2·63	Chestnut	1·60

LATERAL STRENGTH OF MATERIALS.

l = length of beam, in feet.
h = height, b = breadth or thickness, in inches, of the beam where the load is acting.
k = coefficient for the different materials and sections of beams.*
x = coefficient of elasticity of materials (table, page 261) = modulus of elasticity† ÷ 7,000.
f = elastic deflection, in inches.
W = weight, in lbs., which the beam can bear with safety, being about one-quarter of the ultimate load at which the beam would break.

* The value of k varies according to the shape of the beam section (see pages 259-260). For rectangular beams the values are those given in the table, page 261. † See page 263.

EXAMPLE 1 (fig. 382).—A rectangular beam of English oak fastened in a wall projects out $l = 6$ feet 4 inches; $h = 8$ inches, and $b = 5$ inches. Required, what weight, W, it can bear with safety on the end. For English oak, coefficient $k = 25$.

$$W = \frac{25 \times 5 \times 8^2}{6{\cdot}333} = 1{,}263 \text{ lbs.}$$

EXAMPLE 2 (fig. 383).—A cast-iron beam of section fig. 393, with thickness $b = 1{\cdot}25$ inches height $h = 22{\cdot}5$ inches, supported at the two ends in a length $l = 25$ feet. Required, what weight W, it can bear with safety in the middle. For cast iron, coefficient $k = 266$.

$$W = \frac{4 \times 266 \times 1{\cdot}25 \times 22{\cdot}5^2}{25} = 26{,}930 \text{ lbs.} = 12{\cdot}03 \text{ tons.}$$

EXAMPLE 3.—Required the elastic deflection for the same beam and condition as in the last example. Modulus of elasticity $x = 2{,}285$ for cast iron.

$$f = \frac{26325 \times 25^3}{16 \times 2285 \times 1{\cdot}25 \times 22{\cdot}5^3} = {\cdot}79 \text{ inches.}$$

EXAMPLE 4 (fig. 386).—A wrought-iron girder of section fig. 399, consisting of four angle irons of $a = 3{\cdot}5 \times 0{\cdot}5 \times 2 \times 4 = 14$ square inches, the plate being $0{\cdot}5 : 1{\cdot}35 = 0{\cdot}37$ inches thick, and $h = 18$ inches deep by $l = 22$ feet. Required, how much weight, W, evenly distributed, the girder can bear with safety. For wrought iron, coefficient $k = 1040$.

$$W = \frac{8 \times 1040 \times 14 \times 18}{22} = 95{,}302 \text{ lbs.} = 42{\cdot}55 \text{ tons.}$$

If plates are riveted to the angle iron at top and bottom, add that area to a.

EXAMPLE 5 (fig. 404).—The crank $R = 3{\cdot}5$ feet, force $F = 3{,}860$ lbs., length of the shaft $l = 64$ feet, diameter $D = 5{\cdot}25$ inches. Required, the twisting in degrees; the shaft being of wrought iron. For wrought iron, coefficient $x = 4{,}110$.

$$\text{Degrees} = \frac{38{\cdot}4 \times 3860 \times 3{\cdot}5 \times 64}{4110 \times 5{\cdot}25^4} = 10{\cdot}63°.$$

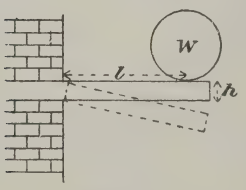

FIG. 382.

$$W = \frac{kbh^2}{l}, \qquad f = \frac{Wl^3}{xbh^3}.$$

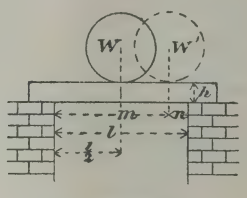

FIG. 383.

$$W = \frac{4kbh^2}{l}, \quad W' = \frac{Wl^3}{4mn}, \quad f = \frac{Wl^3}{16xbh^3}.$$

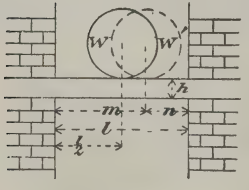

FIG. 384.

$$W = \frac{8kbh^2}{l}, \quad W' = \frac{Wl^3}{4mn}, \quad f = \frac{Wl^3}{32xbh^3}.$$

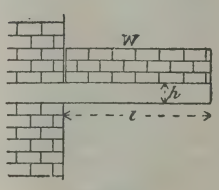

FIG. 385.

$$W = \frac{2kbh^2}{l}, \quad f = \frac{5Wl^3}{2xbh^3}.$$

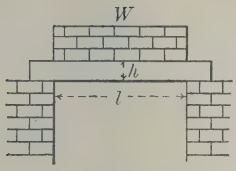

FIG. 386.

$$W = \frac{8kbh^2}{l}, \qquad f = \frac{5Wl^3}{32xbh^3}.$$

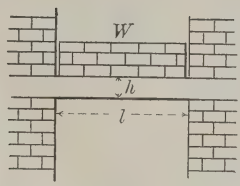

FIG. 387.

$$W = \frac{16kbh^2}{l}, \qquad f = \frac{5Wl^3}{64xbh^3}.$$

$bh^2 = ah.$

a = area of all the four angle irons in square inches.

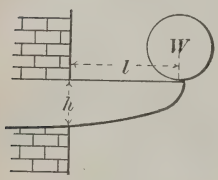

FIG. 400.

A beam fixed at one end and loaded at the other should have the form of a parabola, in which l = abscissa and h = ordinate; y = depth, x = length from W.

$$y = h\sqrt{\frac{x}{l}}.$$

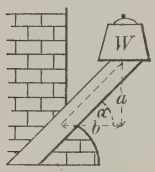

FIG. 401.

$$W = \frac{kbh^2}{l\cos\alpha} = \frac{kbh^2}{b'}.$$

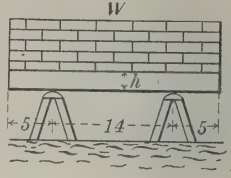

FIG. 402.

$$W = \frac{36kbh^2}{l}.$$

Divide the length into 24 equal parts; place 14 in the middle and 5 at each end.

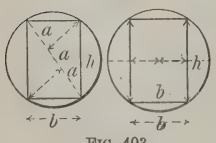

FIG. 403.

TO CUT OUT THE STOUTEST RECTANGULAR BEAM FROM A LOG.

1st case, divide the diameter into 3 equal parts, and draw lines at right angles as represented.

2nd, divide the diameter into 4 equal parts.

(1) $h = 1{\cdot}414\ b$, elastic beams.
(2) $h = 1{\cdot}732\ b$, non-elastic beams.

TWISTING ANGLE OF SHAFTS.

l = length of shaft, in feet. D = diameter of shaft, in inches. R = radius of crank, in feet. F = turning-force, in lbs., applied at pin d at right angles to crank. n = number of revolutions per minute. H = horse-power being transmitted. x = coefficient of Elasticity of metal (See Table, p. 261.).

$$\text{Twisting in degrees} = \frac{38{\cdot}4\text{FR}l}{x\text{D}^4} = \frac{201700\text{H}l}{xn\text{D}^4}$$

Also

$$\text{D} = 4\sqrt{\frac{\text{FR}}{x}} = 70\sqrt[3]{\frac{\text{H}}{xn}}.$$

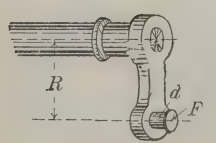

FIG. 404.

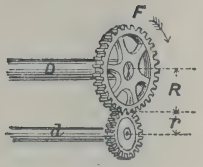

FIG. 405.

l = length of large shaft, D, in feet. D = diameter of large shaft, in inches. d = diameter of small shaft, in inches. R = radius of large wheel, in feet. r = radius of small wheel, in feet. F = turning-point, in lbs., at periphery of large wheel at right angles to radius. n = number of revolutions per minute of large wheel. H = horse-power transmitted by large shaft. x = coefficient of elasticity of metal (see Table below).

$$\text{Twisting in degrees} = \frac{38{\cdot}4\text{FR}l}{x\text{D}^4} = \frac{201700\text{H}l}{xn\text{D}^4}.$$

Also

$$\text{D} = 4\sqrt[3]{\frac{\text{FR}}{x}} = 70\sqrt[3]{\frac{\text{H}}{xn}}. \qquad \text{D} : d = \sqrt[3]{\text{R}} : \sqrt[3]{r}.$$

The absolute safety weight is here taken as one-quarter of the ultimate breaking weight, but when the weight is acting at short intervals one-third might be relied upon, or in pressing circumstances one-half, when the materials in the beams are known to be of good quality; but the latter value should never be exceeded.

CRUSHING STRENGTH OF TIMBER.

Approximately the crushing strength (in direction of grain) of timber in lbs. per sq. in. = weight of wood in lbs. per cu. ft. × 165.

(*Percy W. Smith*, exps. made at Northampton Poly. Inst.—*Engineer*, April 10, 1914.)

SAFE LIMIT OF LOADING.

Wood.	Wrought Iron.	Cast Iron.	
$\frac{1}{10}$	$\frac{1}{3}$ to $\frac{1}{5}$	$\frac{1}{4}$ to $\frac{1}{6}$	of the load which would produce rupture.

Wrought iron will resist about two-thirds as much to crushing as to tension.

A triangular beam which has the same area and depth as a rectangular one is only half as strong as the rectangular one.

A beam of cast iron supported at both ends is six times as strong with the apex up as down if fixed at one end and loaded at free end it is six times as strong with apex down as with it up.

The strength of a cylindrical beam to that of a square one of the same area is as

$$1 : \frac{2}{3}\sqrt{\pi}; \quad \text{or} \quad 1 : 1{\cdot}18 \text{ nearly.}$$

Turning iron down has no important effect on the tenacity.

For good pure iron and steel containing no appreciable quantity of the hardening elements other than carbon

$$T = 52{,}625\ (1 + C^2). \qquad (Weyrauch.)$$

TRANSVERSE STRENGTH OF MATERIALS (*Haswell*).

Reduced to the uniform measure of one inch square and one foot in length; weight suspended from one end.

(Formula : $w = \frac{d^2}{s} \times \frac{20}{6}$; see (10), p. 298.)

EXAMPLE.—To find the breaking weight of a beam of Yellow Pine 18 ft. span, 6 ins. broad, and 12 ins. deep. From table, breaking weight for 1 in. broad and 12 ins. deep is 26·67 cwts.; therefore,

Breaking weight of beam 6 ins. broad = 26·67 × 6 = 160 cwts. (*H. R. Kempe.*)

BRITISH STANDARD SPECIFICATION FOR STRUCTURAL STEEL FOR BRIDGES AND GENERAL BUILDING CONSTRUCTION.*

(No. 15—1912.) (*Abstract.*)

A steel shall be made by the Open Hearth Process (Acid or Basic) unless either process is required or specified, and must not show on analysis more than ·06 per cent. of sulphur or phosphorus.

B steel (which is not intended for bridges, nor for plates ½ in. in thickness or over, or rivet bars) may be made either by the Open Hearth Process (Acid or Basic) unless any one of the four processes is required or specified, and must not show on analysis more than ·08 per cent. of phosphorus, and not more than ·06 per cent. of sulphur.

Plates, sections, and flat bars must show a tensile breaking strength of 28 to 33 tons per sq. in., with an elongation of not less than 20 per cent. for steel of ·375 in. thickness and upwards, and not less than 16 per cent. for steel below ·375 in. thickness.

Round and square bars (other than rivet bars) must show a tensile breaking strength of 28 to 33 tons per sq. in.; the elongation must be not less than 20 or 24 per cent. (according to the form standard test piece used for making the test).

Rivet Bars, 25 to 30 tons per sq. in. breaking strength, and not less than 25 or 30 per cent. elongation (according to the test piece used).

ADMIRALTY TESTS FOR STEEL AND IRON.

TESTS FOR STEEL.

TESTS FOR STEEL ANGLES, ANGLE BULBS, TEES, TEE BULBS, ZED BARS, SHIP PLATES, AND SHIP SHEETS.

(*Abstract.*)

Strips cut lengthwise to have an ultimate tensile strength of not less than 26 and not more than 30 tons per sq. in. of section, with an elongation of 20 per cent. in a length of 8 ins.

Strips cut crosswise or lengthwise 1½ in. wide, heated uniformly to a low cherry-red and cooled in water of about 80° F., must stand bending in a press to a curve of which the inner radius is one and a half times the thickness of the steel tested.

* By permission of the British Engineering Standards Association.

The strips may all be cut in a planing machine, and have the sharp edges taken off.

The ductility of every bar is to be ascertained by the application of the temper test to the shearings, or by bending them cold by the hammer.

Tests for Steel Rivets.

Drawings of 1-inch Ordinary Rivets of the several descriptions specified.

The steel to be free from lamination and injurious surface defects.

One bar is to be taken for tensile testing from every invoice, provided that the number of bars does not exceed fifty. If above that number, one for every additional fifty or portion of fifty. Steel may be received or rejected without a trial of every thickness on the invoice.

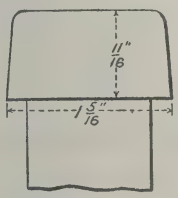

Fig. 406.

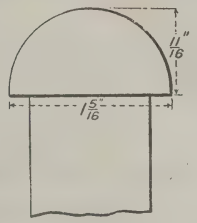

Fig. 407.

The pieces cut out for testing are to be of parallel width from end to end, or for at least 8 inches of length.

When required by the Inspecting Officer a tensile test is to be made from every 'blow.'

The rivets are to be made from British 'acid open-hearth' steel bars having an ultimate tensile strength, for 'boiler' rivets, of not less than 24 and not more than 27 tons per square inch, with

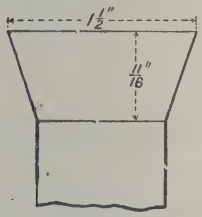

Fig. 408.

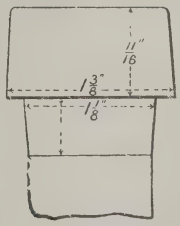

Fig. 409.

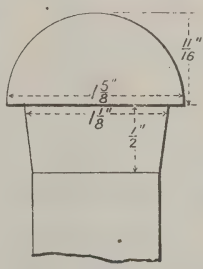

Fig. 410.

a minimum elongation of 25 per cent. in a length of 8 inches; for 'ordinary and screw' rivets, the bars to have an ultimate tensile strength of not less than 26 and not more than 30 tons per square inch, with a minimum elongation of 25 per cent. in a length of 8 inches.

Pieces cut from the bars, heated uniformly to a blood-red, and cooled in water of about 80° F., must stand bending double in a press to a curve of which the inner radius is equal to the radius of the bar tested.

A rivet selected from one hundred to stand the following double tests :—

(*a*) Bending double when cold without fracture, in the manner shown in fig. 411, where the line AB equals one diameter of the rivet.

(*b*) Bending double when hot, and hammered till the two parts of the shank touch, in the manner shown in fig. 412, without fracture.

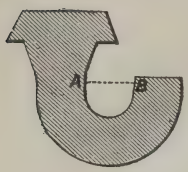

FIG. 411.

FIG. 412.

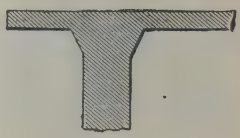

FIG. 413.

(*c*) Flattening of the rivet head, while hot, in the manner shown in fig. 413, without cracking at the edges. The head to be flattened until its diameter is $2\frac{1}{2}$ times the diameter of the shank.

(*d*) The shank of the rivet to be nicked on one side, and bent cold to show the quality of the material.

TESTS FOR STEEL BARS, FLAT, SEGMENTAL, ROUND, SQUARE, AND HEXAGONAL.

Strips cut lengthwise to have an ultimate tensile strength of not less than 30 and not exceeding 35 tons per square inch of section, with an elongation of 20 per cent. in a length of 8 ins. The steel to stand such forge tests, both hot and cold, as may be sufficient to prove soundness of material and fitness for service.

Strips cut lengthwise $1\frac{1}{2}$ ins. wide, heated uniformly to a low cherry red, and cooled in water of a temperature of 82° F., must stand bending double in a press to a curve of which the inner radius is one and a half times the thickness of the steel tested.

INSTRUCTIONS FOR TREATMENT OF MILD STEEL.

All plates or bars which can be bent *cold* are to be so treated, and if the whole length cannot be bent cold heating is to be had recourse to over as little length as possible.

In cases where plates or bars have to be heated, the greatest care should be taken to prevent any work being done upon the material after it has fallen to the dangerous limit of temperature known as a 'blue heat' —say from 600° to 400° F. Should this limit be reached during working, the plates or bars should be reheated.

Where plates or bars have been heated throughout for bending, flanging, &c., and the work has been completed at one heat, subsequent annealing is unnecessary.

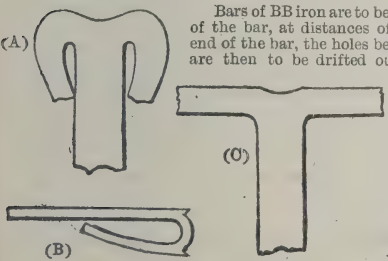
Where simple forge-work has been done, such as the formation of joggles, corners, and easy curves or bends, on portions of plates or bars, and the material has not been much distressed, subsequent annealing is unnecessary.

Plates or bars which have had a large amount of work put upon them while hot, and have had to be reheated, should be subsequently annealed. It is preferred that this annealing should be done simultaneously over the whole of each plate or bar when this can be done conveniently. If it is inconvenient to perform the operation of annealing at one time for the whole of a plate or bar, portions may be annealed separately, proper care being taken to prevent an abrupt termination of the line of heat. If the severe working has been limited to a comparatively small part of a plate or bar, annealing may be limited to the parts which have been heated, the same care being taken to prevent an abrupt termination of the line of heat.

If desired, exceptionally long or quickly curved bars, such as frames, may be formed of shorter pieces with the butts suitably shifted and strapped.

In important cases where any bar or plate shows signs of failure or fracture in working, the details should be forwarded to the Admiralty, in order that instructions may be given as to the disposal of the bar or plate. Failure need not be reported in every case.

It is not necessary to anneal plates or bars after punching as a means of making good damage done in punching. For plating which forms an important feature in the general structural strength, such as the inner and outer bottom plating, deck plating, deck stringers, &c., the butt straps should have the holes drilled or be annealed after the holes are punched. In such bottom plating the countersunk holes should be punched about $\frac{1}{8}$ inch less in diameter than the rivets which are used, the enlargement of the holes being made in the countersinking, which should in all cases be carried through the whole thickness of the plates. All countersinking to be carefully done.



It is important that the whole surface of the bottom plating should be thoroughly cleared of the scale formed in manufacture before any paint or composition is put upon it. All steel plates are to be pickled in the following manner with a view to removing the black oxide or scale:—The plates previous to their being taken in hand for working are to stand a few hours in a liquid consisting of 19 parts of water and one of hydrochloric acid. The plates should be pickled on edge and not laid flat. When plates are removed from the dilute acid bath both the surfaces are to be well brushed and washed to remove any scale which may still adhere to them. They should then be placed in another similar bath filled and kept well supplied with fresh water or be thoroughly washed with a hose, as may be found necessary.

TESTS FOR IRON.

Tests for Bar Iron.

The whole of the samples of every description of iron when tested with the grain are to realise a tensile strength of 22 tons to the square inch.

Forge Test, Hot. BB Bars.

Bars of BB iron are to be punched with a punch one-third the diameter of the bar, at distances of one and a half and three diameters from the end of the bar, the holes being at right angles to one another. The holes are then to be drifted out to one and a quarter times the diameter of the bar. The sides of the holes are then to be split, and the ends must admit of turning back without fracture, as shown by (A).

Broad thick flats may be flattened on the edge to admit of being punched.

A short piece of bar may be flattened down, end on, and punched, as explained above.

Thin flats $\frac{3}{4}$in. thick and below are to be bent to a radius of two and a half times their thickness with the grain, without fracture.

FIG. 414.

B Bars.

The bars are to be punched as in the case of B B iron, and drifted out to one diameter of the bar. Thin flats $\frac{3}{4}$ in. thick and below are to be bent to a radius of three times their thickness with the grain, and if fracture takes place will be rejected. The ends, after punching the holes, must admit of being split and turned back without fracture, as shown by (C).

Forge Tests, Cold.

Samples should be notched and bent, as shown by (B), to show the quality of the iron.

Fire Bars. Forge Test, Hot.

The bars may be flattened at the end to a thickness of $\frac{1}{2}$ in. in either direction.

The standard weight of the bar iron is to be taken at 40 lbs. per sq. ft. for bars of 1 in. thick, and in proportion for bars of all other thicknesses. No bar iron should exceed this prescribed weight, but a latitude of 5 per cent. below this weight will be allowed for thicknesses of $\frac{1}{2}$ an inch and upwards, and of 10 per cent. for less thicknesses. The weight of the iron ordered will be ascertained by weighing the parcel when its weight does not exceed 5 tons, and in lots of 5 tons when its weight exceeds 5 tons.

BRITISH STANDARD SPECIFICATION FOR STRUCTURAL STEEL FOR SHIPBUILDING.*

(No. 13—1910.) (*Abstract.*)

Plates.—The tensile breaking strength of steel plates, determined from Standard test pieces, shall be between the limits of 28 and 32 tons per sq. in. For plates specially intended for cold flanging and marked for identification the tensile breaking strength shall be between the limits of 26 and 30 tons per sq. in. The elongation, measured on a Standard test piece having a gauge length of 8 ins., shall be not less than 20 per cent. for material of ·375 in. in thickness and upwards, and not less than 16 per cent. for material below ·375 in. in thickness.

Angles, Bulb Angles, Channels, etc.—The tensile breaking strength of sectional material, such as angles, bulb angles, channels, etc., shall be between the limits of 28 and 33 tons per sq. in. The elongation, measured on a Standard test piece having a gauge length of 8 ins., shall be not less than 20 per cent. for material of ·375 in. in thickness and upwards, and not less than 16 per cent. for material below ·375 in. in thickness.

Rivet Bars.—The tensile breaking strength of rivet bars shall be between the limits of 25 and 30 tons per sq. in. of section, with an elongation of not less than 25 or 30 per cent. (according to the test piece used).

LLOYD'S TESTS FOR STEEL USED IN SHIPBUILDING. (*Abstract.*)

1. The steel will be required to withstand the tensile and cold and temper bend tests hereafter described, to be applied at the Steel Works under the personal inspection of the Society's surveyors, to samples selected by them from every charge employed in the manufacture of the material, and these samples, when marked by them for testing, should be followed by the surveyors through the different stages of preparation until the tests are completed. At least two tensile tests are to be made from each charge, and an additional tensile test for every variation in thickness of $\frac{3}{20}$ of an inch in the plates or bars made from each charge. A temper bend test is to be made from *each* plate or bar as rolled, and a cold bend test is to be made from each plate or bar tested for tension, and from *all* plates which are to be cold flanged.

2. The tensile tests are to be made upon strips cut lengthwise or crosswise of the plate or bar. They are to be machined to a parallel width for a length of at least 8 inches, and are to have an ultimate tensile strength of not less than 28 and not more than 32 tons per square inch of section. The elongation is to be at least 20 per cent. on a length of 8 inches in samples $\frac{3}{20}$ of an inch and above in thickness, and 16 per cent. in samples below this thickness. Steel plates intended for cold flanging, if specially marked for identification, may be tested to within a minimum limit of 26 tons tensile strength per square inch. Steel angles, channels, and bulbs not exceeding $\frac{1}{20}$ of an inch in thickness may have a maximum tensile strength of 33 tons per square inch of section.

3. Bend tests are to be made upon strips sheared lengthwise or crosswise of the plate or bar. Where the thickness is $\frac{1}{2}$ inch or above, the sharp fin caused by shearing may be removed. They must stand bending double round a curve of which the diameter is not more than three times the thickness.

4. The cold bend tests are to be made from samples as sheared from the plate or bar without annealing.

5. For the temper bends the samples are to be heated to a low cherry red and cooled in water at 82° Fahrenheit.

6. Besides the above tests, samples of the material are to be subjected to additional forge and cold bend tests at the discretion of the surveyors.

7. Should the samples first selected by the surveyors not fulfil the test requirements, duplicate tests may be made; but should these also fail, the plates or bars from which they were cut are to be rejected, and in all such cases further tests are to be made before any material from the same charge can be accepted.

8. Steel used for rivets is to be of special quality, soft and ductile, and samples of the rivets are to be tested by being bent both hot and cold, by flattening down the heads, and by occasional forge tests, in order to satisfy the surveyors of their thorough efficiency.

* By permission of the British Engineering Standards Association.

Iron and Steel Masts, Bowsprits, and Yards.

1. If iron be used in the construction of masts, bowsprits, and yards, it is to be of good malleable quality, quite free from surface or other defects, and to stand a tensile stress of 20 tons to the square inch, and the following bending tests when cold without fracture.

Thickness of Plate.	To Bend Cold through an Angle of		Thickness of Plate.	To Bend Cold through an Angle of

$\frac{6}{16}$	47	15			

2. The plates to be bent over a slab, the corner of which should be rounded with a radius of half an inch.

3. If steel be adopted, it is to be of the quality required for ship plates, and subjected to the same tests.

BUREAU VÉRITAS TESTS FOR IRON AND STEEL USED IN SHIPBUILDING.

(Abstract.)

Tests for Iron.

Tests for Tensile Strength.—The samples to have a minimum tensile strength of 22 tons per square inch of the original section with the fibre, and 18½ tons across the fibre, and an elongation at rupture of 7 per cent. with and 4 per cent. across the fibre on a length of 8 inches.

Hot Bending Tests for Plates.—A strip of at least 2 inches cut from the plate, after being heated to a dull red, shall withstand, without any fracture or cracks, being bent to an angle of 140° with the fibre and 90° across the fibre, the radius of bend being 1½ times the thickness of the plate.

Cold Bending Tests for Plates.—A strip of at least 2 inches cut from the plate shall withstand being bent to the following angles without any fracture or cracks :—

Thickness of Plate.	With the Fibre.	Across the Fibre.	Thickness of Plate.	With the Fibre.	Across the Fibre.
Inch.	Degrees.	Degrees.	Inch.	Degrees.	Degrees.
Under $\frac{1}{50}$	90	40	$\frac{28}{50}$ to $\frac{34}{50}$	35	15
$\frac{13}{50}$ to $\frac{18}{50}$	70	30	$\frac{35}{50}$ to $\frac{40}{50}$	25	10
$\frac{19}{50}$ to $\frac{26}{50}$	50	20			

Inside radius of the bend to be 1½ times the thickness of the plate.

Hot Bending Tests for Angle Bars.—Pieces of angle bars being heated red, must stand the following tests without fracture or cracks :—

1. To have their flanges shut until the outside edges touch. 2. To have their flanges flattened out.

Tests for Steel.

Steel Rivets.

Steel bars for rivets should have a tensile strength of from 24 to not exceeding 29 tons per square inch, with a minimum elongation of 25 per cent. in 8 ins., for bars not less than $\frac{3}{32}$ in. diam.

Quenching Tests.—Pieces cut from the rivet bars are to be heated to a dull red and quenched in water at about 82° F., after which they must be able to stand, without showing any fracture, being bent completely double, the two inner edges being hammered flat against each other for the whole of their length.

Crushing Tests.—Short lengths equal to twice the diameter to be compressed cold to half their length without showing any fracture. Other pieces of the same size, heated to a dull red, must stand being compressed to ¼ of their length, after which they will be punched through with a punch ¾ the diam. of the rivet. No cracks are to be developed under this treatment.

Steel Forgings.

Tensile and Elongation Tests.—The tensile strength may be 27 to 32 tons per sq. in. of the original section. When the strength is 32 tons the elongation shall not be less than 23 per cent.

BOOKS ON STRUCTURAL PRACTICE.

THE PRINCIPLES OF STRUCTURAL MECHANICS.

Treated without the use of Higher Mathematics. By PERCY J. WALDRAM, Lecturer on Structural Mechanics, Architectural School, Central School of Arts and Crafts, London. 368 pages with over 200 Illustrations. 8vo, cloth gilt. 12*s.* 6*d.* net.

The aim is to impart to the reader from the beginning a firm grip of the vital principles which, by enabling him to fully understand the construction of the formulæ he will use, will put him in a position to handle them with certainty.

'Mr. Waldram has left no essential principle unexplained. . . . The success of the book depends not merely on the author's obvious mastery of his subject in all its aspects and details, but even more on his uncommon gift of lucid explanation. He has achieved the difficult feat of writing with simplicity that is never inane, and with amplification that is without superfluity.'—*The Architect's and Builder's Journal.*

DANGEROUS STRUCTURES AND HOW TO DEAL WITH THEM.

A Handbook for Practical Men. By G. H. BLAGROVE, Certified Surveyor under the London Building Act, 1894. Second Edition, much enlarged. With 35 Illustrations. Crown 8vo, cloth. 5*s.* 6*d.* net.

This volume describes ready means for getting over difficulties which frequently occur in practice, and supplies data from which efficient, and at the same time economical, remedies may be designed to counteract evils arising from structural defects.

LIST OF CHAPTERS.—Foundations—Walls—Piers—Arches and Vaults—Beams, Girders, and Floors—Struts, Columns and Stanchions—Ties, Struts, Roofs, and Framed Structures—Lofty Structures—Shoring—Legal Conditions.

SHORING AND UNDERPINNING.

By C. H. STOCK. Third Edition, revised and enlarged by F. R. FARROW, F.R.I.B.A. With 40 Illustrations. Large 8vo, cloth, gilt. 5*s.* 6*d.* net.

STRESSES AND THRUSTS.

A Text-book on their Determination in Constructional Work, with Examples of the Design of Girders and Roofs. By G. A. T. MIDDLETON, A.R.I.B.A. Third Edition, revised, containing new chapters on Designing Steel Joists and Steel Plate Girders. With 170 Illustrations. Crown 8vo, cloth, gilt. 5*s.* 6*d.* net.

in a length of 4 ins. For less than 32 tons the elongation shall increase in inverse ratio to the strength; therefore 27 tons elongation shall be 26 per cent.

Cold Bending Tests.—A test piece 1 in. square and about 10 ins. long, cut from the forging, must stand being bent double in the form of a U, without showing any sign of a fracture or crack, the internal radius of bend being ¾ in.

Steel Castings.

For stems, stern frames, condensers, engine columns, etc., the tensile strength may reach up to 35 tons per sq. in. of original section, or even to 38 tons when a very fluid steel is required for thin pieces, such as sole plates.

For engine pieces exposed to constantly varying stresses, the upper limit of tensile strength is to be lower than 35 tons. For crank shafts, for instance, it should not exceed 30 tons.

The elongation and tensile strength will be in accordance with the following table.

Cold Bending Tests.—A test piece 1 in. square must be able, without showing any signs of fracture, to be bent to the angle given in the table, with an internal radius of 1½ in.

Percussion Tests.—Pieces 1 in. square, resting in a horizontal position on two supports (knife-edges) spaced 6½ ins. apart, must be able to resist without any fracture a series of shocks caused by a weight of 40 lbs. falling upon them from a gradually increasing height, beginning at 3½ ft. and ending at 5 ft., the increase between two successive tests being 2 ins.

(See also pp. 272 and 273.)

Cold and Hot Crushing Tests.—Short lengths equal to twice their diameter to be compressed cold to half their length; other pieces of same length heated to a dull red must stand being compressed to ¼ of their length, after which they are to be punched through, with a punch having a diameter equal to ⅞ that of the rivet.

Remarks

Tensile and Bending Tests.—One-half of the test pieces to be cut lengthwise from the plate, and the other half crosswise.

Quenching Tests.—The strips to be heated to a dull red and quenched in water of 82° F.

Number of Tests.—The number of tests to be made shall vary with the thickness as shown in the annexed table:—

One test for each piece will be required when the number of the charge is not known to the surveyor.
Steel for Welding Purposes	L=4 ins. D=$\frac{9}{16}$″	23·5	24·75	under 13	30	*Tests.*—For the forge tests two bars are to be lap-welded at white heat. The weld must be examined after the first or second blows of steam hammer. The test piece must then be crushed by steam-hammer, being placed perpendicular to same. Before re-heating a hole must be punched transversely through the weld by a conical punch, to show the nature of the welded parts and to make sure that the joint is in every respect satisfactory. *Number of Tests.*—One tensile and elongation test. Two series of tests for each charge.			
Nickel Steel Forgings 3·25% nickel 0·35% carbon	L=4 ins. D=$\frac{9}{16}$″	37	42	under 13	20	*Percussion Tests.*—Test piece 1 in. square placed on knife edges 6½ ins. apart. Test weight, 40 lbs. Fall, 9 feet. Number of blows, 15.			The test pieces to be taken after the forging is annealed. *Number of Tests.*—One for each piece.
Steel Castings.	Working length 4 inches. Diameter turned to $\frac{9}{16}$″	28 31 35 38	42 ,, ,, ,,	under 13 ,, ,, ,	In 4 ins. 16% 14 12 10	Test piece 1 in. square	1½ ins.	90° 90° 90° 90°	*Percussion Test.*—Test piece 1″ square placed on knife edges 6½″ apart. Test weight, 40 lbs.; fall, 3½ ft. to 5 ft.; the increase between two successive tests to be 2″. *Hammering Test.*—Hung up freely and hammered. Weight of hammer at least 7 lbs.	In every case one set of tests shall be made from each charge when plates or bars are produced from different charges. The maximum tensile strength shall be: 35 tons for engine castings subject to live load. 30 tons for shafting and mast fittings, and for cast steel anchors. *Number of Tests.*—One for every charge, and one for every large casting.

INDIAN GOVERNMENT TESTS FOR STEEL.

(Abstract.)

Steel Plates (except for Boilers) and Sheets.

Strips cut crosswise or lengthwise are to have an ultimate tensile strength of not less than 26 and not exceeding 30 tons per square inch of section, with an elongation of not less than 20 per cent. in a length of 8 inches. *Sheets of ⅛ inch thickness and under will not be subjected to this test.*

Strips cut crosswise or lengthwise 1½ inches wide, heated uniformly to a low cherry red, and cooled in water of about 80° Fahrenheit, must stand bending double in a press to a curve of which the inner radius is one and a half times the thickness of the steel tested.

The ductility of every plate or sheet will be ascertained by the application of the temper test to the shearings, or by bending them cold and untempered by the hammer. The machine test will be applied to not less than 2 per cent. of the plates or sheets of each thickness subject to this test. Any which do not stand the tests will be rejected.

Bar Steel (all Sections).

The steel is to have an ultimate tensile strength of not less than 26 and not exceeding 30 tons per square inch of section, with a minimum elongation of 20 per cent. in a length of 8 inches.

Pieces heated uniformly to a low cherry red, and cooled in water of about 80° Fahrenheit, must stand bending double, in a press, to a curve of which the inner radius is one and a half times the thickness or diameter of the bar tested.

The ductility of the bars will be ascertained by the application of the temper test to the shearings, and by bending them cold and untempered by the hammer. The machine test will be applied to not less than 2 per cent. of the bars of each section.

Sample pieces will also be taken for testing the welding qualities of the steel by welding two pieces together and bending it the way of the weld when cold.

Steel Boilers.

Plates.

All plates are to be free from lamination and injurious surface defects, and their surfaces are to be quite fair and flat.

The strips are to be of parallel width for at least 8 inches of their length, and are to be cut in a planing machine and have the sharp edges taken off.

Strips cut crosswise and lengthwise are to have an ultimate tensile strength per square inch of original section as follows :—

(*a*) For shell and other plates which are not exposed to flame and which will not be flanged, not less than 27 tons and not exceeding 30 tons, with an elongation of not less than 20 per cent. in a length of 8 inches.

(*b*) For plates which are exposed to flame and plates which are to be flanged, not less than 24 tons and not exceeding 27 tons, with an elongation of not less than 25 per cent. in a length of 8 inches.

Strips cut crosswise and lengthwise 1½ inches wide, heated uniformly to a low cherry red, and cooled in water of about 80° Fahrenheit, must stand bending in a press to a curve of which the inner radius is one-and-a-half times the thickness of the steel tested.

The ductility of every plate will be ascertained by the application of both of these tests to the shearings, both crosswise and lengthwise in every case.

Strips from the plates for furnaces and other parts exposed to flame, and from those requiring flanging, are, in addition, to be tested by welding and forging.

Angles, Flat Bars, etc.

These will be subject to the same tests as plates, but lengthwise only.

Rivets.

The steel for rivets is to have an ultimate tensile strength of not less than 25 and not exceeding 27 tons per square inch of section, with a minimum elongation of 25 per cent. in a length of 8 inches.

The rivets are to stand the following forge tests :—

(*a*) Bending hot and cold without fracture through an angle of 180°.

(*b*) Flattening of the rivet head, while hot, without cracking at the edges. The head to be flattened until its diameter is two and a half times that of the shank.

(*c*) The shank of the rivet to be nicked on one side, and bent over to show the quality of the steel. The shank must bear this test without breaking off short.

BURSTING STRENGTH OF TUBES.

Let p = bursting pressure in lbs. per sq. in. inside tube.
D = outside diameter of tube in inches.
d = inside " " "

Then

$$p = \frac{D^2 - d^2}{D^2 + d^2} f.$$

Values of f.

Steel (60° F.) . . . 95,000	Wrought iron (60° F.) . . 50,000	Copper (rolled) (60° F.) . 35,000
" (800° F.)* . . . 28,800	Cast iron (60° F.) . . . 20,000	" " (640° F.)* 14,700
	Brass (rolled) (60° F.) 30,000	

If t = thickness of tube, and $n = \frac{d}{t}$, then

$$p = \frac{2}{n + 1 + \frac{1}{n+1}} f = \kappa f.$$

* *Durston.* *(H. R. Kempe.)*

EXAMPLE (1).—What is the bursting strength of a wrought-iron tube whose bore is 2 ins. (d), and thickness ·1 inch (t)?

$$n = \frac{d}{t} = \frac{2}{\cdot 1} = 20.$$

κ corresponding to 20 is ·095; therefore

$$p = \cdot 095 \times 50{,}000 = 4{,}750 \text{ lbs per sq. in.}$$

If the value of n is not a number whose exact value can be found in the table, then multiply the excess which n has above the next lower value in the table by the difference between the value of κ corresponding to this lower value and the next higher value; then add the result to the lower value of κ, thus:

EXAMPLE (2).—What is the bursting strength of a wrought-iron tube whose bore is 2 ins. (D.), and thickness 1·2 ins. (t)?

$$n = \frac{D}{t} = \frac{2}{1 \cdot 2} = 1 \cdot 67;$$

next lower value of n in the table is 1·6, and

Excess of 1·67 over 1·6 = ·07. Value of κ corresponding to 1·6 = ·670.

Next higher value of κ = ·651;

then

·670 − ·651 = ·019; ·019 × ·07 = ·00133; ·00133 + ·651 = ·65233, the required value of κ;

therefore bursting strength p is

$$p = \cdot 652 \times 50{,}000 = 32{,}600 \text{ lbs. per sq. in.}$$

Values of p for values of $\frac{d}{t}$ exceeding 60 may be calculated very approximately by the formula

$$p = \frac{2}{n+1}, \text{ or } \frac{2t}{d+t}.$$

EXAMPLE (3).—What is the bursting strength of a steel tube 3 ins. in bore and ·045 inch thick?

$$p = \frac{2 \times \cdot 045}{3 + \cdot 045} \times 95{,}000 = \cdot 0296 \times 95{,}000 = 2{,}810 \text{ lbs. per sq. in.}$$

If t is *very* small compared with d, then

$$p = \frac{2t}{d}.$$

STRENGTH OF STEEL TUBES.

1. The length of tube, between transverse joints tending to hold it to a circular form, has no practical influence upon the collapsing pressure of a commercial lap-welded steel tube so long as this length is not less than about six diameters of tube.

2. The formulæ, as based upon the present research, for the collapsing pressure of modern lap-welded Bessemer steel tubes are as follows:—

$$P = 1{,}000 \left(1 - \sqrt{1 - 1{,}600 \frac{t^2}{d^2}}\right) \quad \text{(A)} \qquad P = 86{,}670 \frac{t}{d} - 1{,}386 \quad \text{(B)}$$

Where

P = collapsing pressure, in pounds per square inch; d = outside diameter of tube in inches; t = thickness of wall in inches.

Formula (A) is for values of P less than 580 lbs., or for values of $\frac{t}{d}$ less than 0·023, while formula (B) is for values greater than these.

These formulæ, while strictly correct for tubes that are 20 ft. in length between transverse joints tending to hold them to a circular form, are at the same time substantially correct for all lengths greater than about six diameters. They have been tested for seven diameters, ranging from 3 ins. to 10 ins., in all obtainable commercial thicknesses of wall, and are known to be correct for this range.

3. For the most favourable practical conditions—viz. when the tube is subjected only to stress due to fluid pressure, and only the most trivial loss could result from its failure—a factor of safety of 3 would appear sufficient.

4. When only a moderate amount of loss could result from failure, use a factor of 4.

5. When considerable damage to property and loss of life might result from a failure of the tube, then use a factor of safety of 6.

6. When the conditions of service are such as to cause the tube to become less capable of resisting collapsing pressure, such as the thinning of wall due to corrosion, the weakening of the material due to overheating, the creating of internal stress in the wall of the tube due to unequal heating, vibration, etc., the above factors of safety should be increased in proportion to the severity of these actions. (*R. T. Stewart.*)

(*Kirkaldy.*)

Allowable Pressure in Thick Hollow Cylinders.

If P = allowable pressure in lbs. per sq. in.; S_t = allowable working stress of the material in lbs. per sq. in.; K = ratio of the external diameter to the internal diameter; then

$$\frac{P}{S_t} = 0{\cdot}6\,\frac{K^2 - 1}{K^2}.$$

(*Gilbert Cook and Andrew Robertson*, '*Engineering*,' Dec. 15, 1911.)

Chart for Computing Allowable Pressure in Thick Hollow Cylinders.

The chart, fig. 415, prepared by Herman Steiger from the foregoing formula, may be used to determine the allowable pressure for a given cylinder, or to determine the dimensions of a cylinder for a given internal pressure.

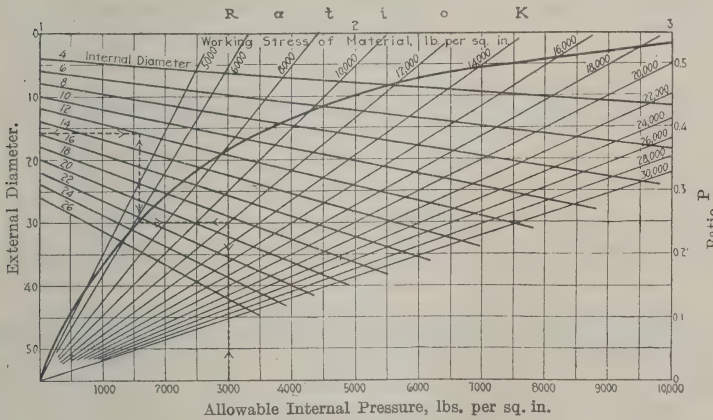

Fig. 415.

Example 1.—Suppose a steel cylinder is 16 ins. outside diameter and 12 ins. inside diameter, and the metal is good for 12,000 lbs. per sq. in. working stress. It is desired to find the allowable

internal pressure.—From the given external diameter, 16 ins., on the vertical scale move horizontally, as shown by the dotted line, to the line marked 12 ins. internal diameter. From this point move vertically to the heavy curved line and then horizontally to the line marked 12,000 lbs. working stress. Directly below this point read off the allowable pressure on the horizontal scale, 3,000 lbs. per sq. in.

Example 2.—Suppose it is desired to know the thickness of a cylinder to stand 3,000 lbs. per sq. in. pressure when the internal diameter is 12 ins. and the allowable stress is 12,000 lbs. per sq. in.—From the 3,000-lb. point on the horizontal scale move upward to the 12,000-lb. stress line and then horizontally to the curved line. From here move vertically to the 12-in. internal diameter line and read off the external diameter, 16 ins., on the left-side scale. (*'Power.'*)

STRENGTH OF IRON CHAINS.

(1.)

A stud link chain of equal dimensions will, within the elastic limit, bear from 20 to 25 per cent. more load than the open link chain. The ultimate strength of the stud link chain is probably less than that of the open link chain.

In the formulæ for the safe loading of chains given by the leading authorities on machine design, the maximum stress to which the link is subjected seems to be underestimated, and the constants are such as to give maximum stresses of from 30,000 lbs. to 40,000 lbs. per sq. in. for full load. The following formulæ are applicable to chains of the usual form :—

$$\left.\begin{aligned} P &= 0{\cdot}4\ sd^2, \text{ for open links} \\ P &= 0{\cdot}5\ sd^2, \text{ for stud links} \end{aligned}\right\} \quad \text{(A)}$$

as compared with Professor Unwin's formulæ :—

$$\begin{aligned} P &= 6\ d^2, \text{ for open links,} \\ P &= 9\ d^2, \text{ for stud links,} \end{aligned}$$

where P denotes the safe load, d the diameter of the stock, and s the maximum permissible tensile stress.

(*C. E. Goodenough and L. E. Moore.*)

In formulæ (A), if d is the diameter in inches (or decimals of an inch) of the bar iron of which the chains are made, and if s be taken of the mean value 35,000, then P in tons will be

$$P = 0{\cdot}4 \times \frac{35000}{2240} d^2 = 6{\cdot}25 d^2, \text{ for open links,}$$

$$P = 0{\cdot}5 \times \frac{35000}{2240} d^2 = 7{\cdot}8 d^2, \text{ for stud links.}$$

(2.)*

d = Number of eighths of an inch in diameter of rod iron of which chain is made ; S = Safe working load in tons.

$$S = d^2 \div 10.$$

(See also Section XVII, Cranes and Crane Appliances, p. 794.)

*See paper read by Mr. Daniel Adamson, M.I.Mech.E., before the Inst., of Mech Engrs. 1913.

(3.)

Ultimate Strength of a Chain.

The ultimate, or breaking, strength of a chain is usually found to lie between 1·5 and 1·7 (average 1·66) times the ultimate strength of the straight bar or stock from which it is formed, instead of twice that amount, as might at first thought be expected because of the doubling of the bar in forming the link.

Safe Load on a Chain.

For chains with open links of the usual form,

$$F = 2{\cdot}5 \times \frac{P}{D^2},$$

For chains with stud links,

$$F = 2 \times \frac{P}{D^2},$$

where, F = extreme fibre stress in tension, in lbs. per sq. in.; D = diameter of stock in ins.; P = chain load, in lbs.

The safe loads for open-link chains given in the table, page 280, have been computed by this formula, using the value of 12,000 lbs. per sq. in. for the allowable maximum fibre stress, and assuming an elastic limit of 24,000 lbs. per sq. in., thus assuring in every case an actual safety factor of at least 2, based on the elastic limit of wrought iron, or more if open-hearths

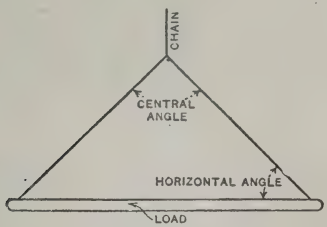

Fig. 416.

low-carbon steel is used. For material possessing an elastic limit of 30,000 lbs. per sq. in., a fibre stress of 15,000 lbs. per sq. in. may be assumed, in which case the tabular values should be increased 25 per cent.

The nominal size of a chain is indicated by the diameter of the steel or iron of the link. The central angle (fig. 416) is the angle between the parts of a double sling; the horizontal angle is the angle between each part of a double sling and a horizontal line. The horizontal collapsing force is the force tending to crush together the load carried between the points of attachment of a double sling. This force must be taken into consideration in the case of hollow castings on similar loads; it may be found by multiplying the total load by the 'factor' given in the table. The safe values given in the table are for single chains. When used double, the values given should be multiplied by 2, and so on in proportion. In a double sling, properly adjusted, each leg carries only its portion of the load; when a double sling is attached to a single chain of the same size, the safe load for the single chain only should be used. When a heavy chain is used in connection with a lighter double sling, the safe load is the smaller of the two tabular values; that is, it is either equal to the safe load of the chain that carries the total load, or to twice the safe load of one part of the sling, whichever value is the smaller.

Example: A safe load for a single $\frac{7}{8}$-in. chain is 3,700 lbs. If this chain is used with a double $\frac{7}{8}$-in. sling attached to the load so as to make a central angle of 15 degrees, each part of the sling has a carrying capacity of 1,880 lbs., so that the double sling has practically the same safe load as the single chain, namely $2 \times 1{\cdot}880 = 3{,}760$ lbs. If a $\frac{7}{8}$-in. double sling is used with this chain, and so attached as to make a central angle of 30 degrees, each part of the sling can safely carry only 1,160 lbs., or a safe load for the double sling so attached is only 2,320 lbs., which, being less than that for the straight chain itself, constitutes the safe load for the combination.

SAFE WORKING LOADS FOR SINGLE OPEN-LINK CHAINS.*

For stud links increase these values 25 per cent.

* The elastic limit has been assumed as 24,000 pounds per square inch and the maximum allowable fibre stress as 12,000 pounds per square inch.†

If a 1-in. chain is used with a $\frac{7}{8}$-in. double sling making a central angle of 15 degrees, the double sling is capable of carrying a safe load of $2 \times 2{,}675 = 5{,}350$ lbs.; but the straight chain itself can carry a safe load of only 4,800 lbs., which is therefore the proper safe load of the combination. The collapsing or crushing force of this load is $0{\cdot}06 \times 4{,}800 = 288$ lbs. Chains that have been overloaded to such a point as to cause fatigue can be detected, when struck a sharp blow with a hammer, by a characteristic ring. Further proof of such condition can be obtained by placing the link edgewise on an anvil and striking it several sharp blows with a sledge; if it is fatigued, the link will fracture sharply with a decided crystalline appearance. In case a chain is found to contain a link of such a nature, the entire chain should be discarded for all overhead lifting purposes where life might be endangered.

CONNECTING RING.

The connecting ring must be designed to resist the same safe load as the chain. The following formula is recommended :—

$$P = \frac{0{\cdot}617Fd^3}{D} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (B)$$

where, P = safe load; d = diameter of stock in ring;
F = fibre stress of material used; D = main diameter of ring.

(Engineering Experiment Station of the University of Illinois, U.S.A.)

† This is a much lower limit than in the case of British practice (1) and (2).—H. R. KEMPE.

Precautions in the Use of Chains.

The third Safety Pamphlet issued by the Home Office (Dec. 1920), deals with the use of chains and other lifting gear. It is pointed out that accidents should, according to law, be reported to the factory inspector. The safe working load for chains is given, in tons, as six times the square of its diameter (the American rule is $2{\cdot}8d^2$—which gives a factor of safety of 4·5).

TABLE OF SAFE WORKING LOADS FOR TWO-LEGGED SLINGS.

Chain Diameter, Ins.	Safe Working Loads in Tons and Cwt. for given Angles between Legs.					
	0 Deg.	30 Deg.	60 Deg.	90 Deg.	120 Deg.	150 Deg.

NOTES.

(4) The maximum working load for any short or close-link chain should not exceed $6d^2$ tons, when used under normal conditions without shock ; $5d^2$ tons, where there is any special danger to life or limb, or $3{\cdot}5d^2$ tons where the chain is subjected to shock or heavy wear, or is used for lifts of molten metal or heated liquid ; d being the diameter in inches of the iron of the chain. The maximum working load for a long-link chain should not exceed two-thirds of that for a short-link chain of the same diameter.

(5) When chain slings with two or more legs are used with the legs inclined, care should be taken to ensure that the maximum load in each leg does not exceed that given in recommendation (4) above—see also table.

(8) Slings or other chains should never be shortened by tying knots in them ; and wood or other suitable packing should be provided to prevent the links coming in contact with corners of loads of hard material.

(11) All chains and other lifting appliances should—(*a*) If used for lifting in connection with molten metal or molten slag, be examined at least once in every month and be annealed at least once in every six months ; or (*b*) if used in connection with lifting machinery or plant operated mechanically or electrically, or used for lifting in metal foundries other than that mentioned in paragraph (*a*) above, be examined at least once in every three months and be annealed at least once in every twelve months ; or (*c*) if used for classes of lifts other than those mentioned in (*a*) and (*b*) above, e.g., in connection with hand cranes, be examined at least once in every six months and be annealed at least once in every two years ; or (*d*) if used for holding down any crane or other lifting machinery upon a stage or platform should be examined as far as reasonably practicable, *in situ*, at least once in every three months, and be fully examined and annealed at least once in every twelve months, unless the nature of the operations preclude such examinations and annealing.

(12) A chain or other appliance should not be used for lifting its maximum working load if the wear at any part exceeds 10 per cent. of the nominal dimension of that part, or for lifting any load if it has been subjected to a severe shock or is deformed or otherwise injured.

(13) A chain or other appliance which has been altered or repaired should be re-tested before use.

STRENGTH OF IRON RINGS.

(1.)

Let a = the area in square inches of one side of the link A, which is known when the load to be lifted has been decided on.

Then $\frac{R}{d} \times a$ = area of iron in one side of the ring required in square inches.

The radius R being first decided upon, d, the diameter of the iron, must be assumed, and the area of the ring calculated by the above formula.

Having got the area of one side of the ring in this way, find the diameter to correspond to it.

Should the result be greater than the first assumed diameter of d, the ring is too weak; if the result is less than the first assumed diameter of d, the ring is too strong. A fresh size for d must in either case be adopted until the diameter corresponding to the area calculated by the formula equals the originally assumed diameter of d. This dimension will be the size required. (*Sutton.*)

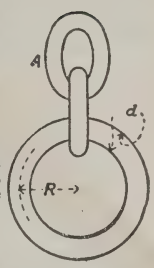

FIG. 417.

(2.)

Let d = diameter of iron of ring in inches; R = radius of ring in inches; d_1 = diameter of iron of chain in inches to lift the given load, the load being in tons.

Then

$$d = \sqrt[3]{R d_1^2}.$$

(See also (B) page 280.)

STRENGTH OF ROPES.*

The following rules are useful for roughly estimating the safe working loads for ropes and chains:—

Hemp Ropes.

C = Circumference of rope in inches; S = Safe working load in cwts.

$$S = C^2.$$

Steel Ropes.

C = Circumference of rope in inches; S = Safe working load in tons.

$$S = C^2 \div 2.$$

From a series of 368 tests of Manila rope in sizes from ½ in. to 4½ in. diameter carried out at the United States Bureau of Standards during the past three or four years it has been found that the average breaking strength of the rope is very closely represented by the formula

$$L = 5000\, d\,(d + 1).$$

TESTING MANILA ROPE.

This test has been adopted by the United States Bureau of Standards: Free the rope from oil, soak it for 20 seconds in a solution of bleaching powder acidulated with acetic acid, rinse in water and then in alcohol, and finally expose the fibres of the rope for a minute to the fumes of ammonia. Manila fibre turns russet brown, while all other rope fibres turn a cherry red.

PRESERVATION OF MANILA AND WIRE ROPES.

Manila ropes and slings and wire cables through neglect do not last as long as they should, because they are allowed to decay and rust, and apart from the waste of not preserving them they are a source of accidents. Ordinary ropes should be painted over with beeswax and resin, about equal parts of each, melted together, and applied with a paint brush. The rusting of wire cables and ropes is arrested by treating them with a mixture of tallow and oil, seven or eight pounds of melted tallow to a gallon of oil, lime being added, when the mixture is cold, until it is thick. The composition is then applied with a brush.

Hemp ropes may be preserved by dipping them when dry into a solution of 1 oz. of sulphate of copper dissolved in 2½ pints of water, and kept in this solution for four days, afterwards being dried; the rope should then be soaked in a solution of 5 ozs. of soap dissolved in 2½ pints of water, and again dried.

---

* See paper read by Mr. Daniel Adamson, M.I.Mech.E., before the Inst. of Mech. Engrs. 1912.

Experience has shown that wire ropes of compound construction, subjected to corrosion influences, are likely to deceive engineers as to the strength remaining in them. Where reduction of diameter or circumference of the rope has taken place, not accounted for by the evidence of wear, the part of the rope under examination should first be fully loaded and then relieved of the load. Any noticeable difference in circumference in these circumstances, and the slackening of the outside wires when the load is off, will indicate that internal corrosion has taken place. The extent of corrosion inside the strand can only be estimated by the slackness of the outside wires. The corrosion between the strands can be further examined by untwisting the rope or displaying the strands sufficiently with a marlin-spike.

STRESSES ON BEAMS AND GIRDERS

When designing framed structures, the external forces (or those acting *on* the structure, are always known or assumed, and from these, and the configuration or design of the structure, the internal stresses set up in the several portions of the structure can be determined.

The external forces may be assumed as acting transversely, i.e., at right angles to the beam, or girder, the supporting forces or reactions necessarily acting parallel to and in the opposite direction to the applied forces. Where any force acts other than transversely, it should be resolved into two component forces, one acting in the direction of the length of the beam (and causing compression or tension throughout the complete cross-section), and the other acting transversely ; to obtain the total stress at any section of the beam, the tension or compression due to the former component must be added algebraically to the stress from the transverse component.

The beam or girder, whatever its form may be, will tend to shear transversely, and to bend under any system of loading, and the values of these tendencies at any section are termed the 'shearing stress ' and the 'bending moment' values at that particular section.

At any vertical section throughout a beam the shearing stress to be resisted is the algebraic sum of all the vertical forces acting to the right or the left of the section chosen ; the forces being reckoned, say, as positive or negative as they act in an upward or downward direction.

For any series of transverse forces W_1, W_2, W_3, etc., acting to one side of the chosen vertical section, the general formula for the shearing stress is :—

$$S=\Sigma W=\pm W_1 \pm W_2 \pm W_3, \text{ etc.} \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

At any vertical section throughout a beam, the bending moment to be resisted is the algebraic sum of the moments of the several vertical forces acting to the right or left of the chosen section, these moments being reckoned, say, as positive or negative as they tend to turn the beam about the section line in a clock-way or anti-clock way.

Thus, for any series of transverse forces W_1, W_2, W_3, etc., acting at the several horizontal distances l_1, l_2, l_3, etc., from the chosen vertical section, the general formula for the bending moment is :—

$$M=\Sigma(Wl)=\pm W_1 l_1 \pm W_2 l_2 \pm W_3 l_3, \text{ etc.} \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

(In the case of uniformly distributed loads the value W is that for the total load under consideration, the horizontal distance being then measured from the chosen section to the centre of the load.)

Where the supports to a beam are not more than two in number, and the ends of the beam are free, the reactions or supporting loads can readily be found by the law of the lever. These values are then added to the list of external forces, and the shearing forces and bending moment values calculated from formulæ (1) and (2).

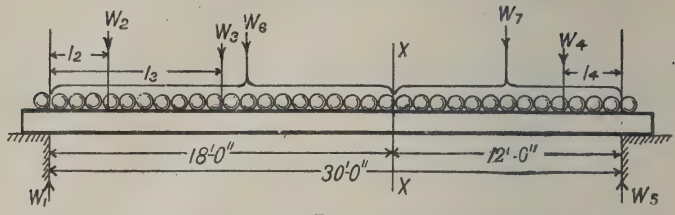

FIG. 1.

EXAMPLE:—A beam 30 ft. clear span between reactions carries three concentrated loads of 150 lbs. each, spaced as shown (fig. 1); weight of beam 60 lbs. per linear foot. l_2, $l_4 = 3'\text{-}0''$, $l_3 = 9'\text{-}0''$.

Reaction, left $= W_1$.	Reaction, right $= W_5$.
Beam $= 30 \times 60 \times \frac{1}{2} = 900$ lbs.	$= 30 \times 60 \times \frac{1}{2} = 900$ lbs.
Load W_2 $= 150 \times \frac{30-3}{30} = 135$,,	$= 150 \times \frac{3}{30} = 15$,,
,, W_3 $= 150 \times \frac{30-9}{30} = 105$,,	$= 150 \times \frac{9}{30} = 45$,,
,, W_4 $= 150 \times \frac{30-27}{30} = 15$,,	$= 150 \times \frac{30-3}{30} = 135$,,
Total $= 1{,}155$ lbs.	Total $= 1{,}095$ lbs.

Shearing stress at Section XX, fig. 1, calculated from left:—

Formula (1) $S = W_1 - (W_2 + W_3 + W_6)$
$= 1{,}155 - [150 + 150 + (60 \times 18)] = 224$ lbs.

Calculated from right $S = W_5 - (W_4 + W_7)$
$= 1{,}095 - [150 + (60 \times 12)] = 224$ lbs.

Bending moment at Section XX, fig. 1, calculated from left:—

Formula (2) $M = W_1 l_1 - (W_2 l_2 + W_3 l_3 + W_6 l_6)$
$= 1{,}155 \times 18 - [(150 \times 15) + (150 \times 9) + (18 \times 60 \times 9) = +7{,}470$ ft. lbs.

and from right, $M = -W_5 l_5 + (W_4 l_4 + W_7 l_7)$
$= -1{,}095 \times 12 + [(150 \times 9) + (60 \times 12 \times 6)] = -7{,}470$ ft. lbs.

Graphic diagrams for shear and bending moment values can be drawn so as to represent these values at all points throughout the length of a beam or girder, and such diagrams can always be used when setting out some preliminary or trial design, or checking a design; when carefully and accurately drawn they can be utilised directly in designing all ordinary structures, thus saving a large amount of time and labour which would be necessary if all required values were calculated arithmetically. Since these diagrams show the variations in stress throughout the beam, they can be further utilised to set out the sections or scantlings of the web and flange members, such as the thickness of the web or shear resisting members, and the cut-off in the flange plates or bending resisting members.

The tables of bending moments and shearing stresses given on pages 292 and 293 embrace all simple conditions for concentrated or uniformly distributed loads. Any complex loading occurring in practice can always be resolved into a series of simple loadings; so that diagrams for each simple loading can be drawn on one base line, and these diagrams combined to produce the required diagram for the complex loading, by adding together the several ordinates at any desired section. An example of this is given in fig. 2.

It should be noted that for any series of concentrated loads the bending moment line will form a polygon, the line changing its direction over each of the loaded points; at each of these points the shearing stress is suddenly changed in value, and the shearing stress diagram takes a stepped outline. For a uniformly distributed load, the bending moment line is always a parabolic curve, while the shearing stress changes by a regular gradation.

When beams or girders are of varying depth, the diagrams on pages 292 and 293, which are based on the condition of uniform depth, must be adjusted, for the following reason:—By formula (3) it will be obvious that the flange stresses are dependent on the depth, and, in fact, *vary inversely as this depth*; it is, therefore, necessary to alter the bending moment heights in the *inverse ratio to the alteration in depth of the beam.* Reducing the depth of a beam increases the bending moment value, and necessitates the increasing of the height of the bending moment diagram. Fig. 3 and brief explanation accompanying same will indicate how this adjustment can be readily carried out.

Where the shearing stress diagram is intended to be used in setting out the varying thickness of the web plate of a beam, the shear stress diagram must similarly be adjusted by altering its heights in *inverse ratio to the alteration in depth of the beam*; a shallower girder necessitates a thicker web, when the shear value remains unaltered (see fig. 3).

When these graphic diagrams on pages 292 and 293 are used in connection with panel or lattice girders, a modification is necessary, since the flange stress remains constant between the points of connection of flange to lattice bars; the diagram becomes stepped in outline, and may not be the same in both flanges (see fig. 4).

For the majority of the simple panel or lattice girders met with in practice, the various stresses can be most readily obtained by the reciprocal diagram method or by the method of moments.

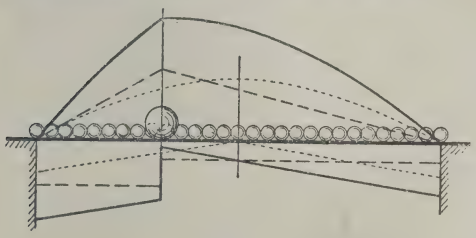

FIG. 2.

This example shows a free-ended beam supporting a uniformly distributed load (see Table 1, type (d)) the bending moment and shearing stress diagrams being indicated by dotted lines; and a single concentrated load (see Table 1, type (e)), the two diagrams being here indicated by broken lines. The combined diagrams for these two loads are shown by full lines, and are got by adding together the two heights at any section, to obtain the new height there.

In some cases, as for girders with fixed ends, negative moments may occur, and these must obviously be added algebraically to the positive moments to obtain the required new combined height.

This figure shows the effect on the bending moment and shearing stress diagrams due to a change in the depth of the girder, and a simple graphic method of indicating this effect on change. The left half of fig. 3 shows diagrams for a free-ended girder of uniform depth carrying a uniformly distributed load (Table 1, type (d)); in the right half of the figure the depth of the girder is reduced as indicated. From the centre to the first section line the depth is uniform, so that the bending moment line remains unaltered, but beyond this section the *height of diagram must be increased in proportion to the reduction in depth of the girder*. This increase can be obtained graphically thus: — Take the vertical section line at point *a*, and draw any line *ab*; on this line mark off *ab* equal to the centre depth of the girder, and *ac* equal to the reduced depth at this section; join *cd* (*d* being at the point of intersection of original diagram line and section line), and draw *be* parallel to *cd* and cutting the section line at *e*. It is obvious that the new vertical heights *ae* and *ad* are proportionate to the original depth and the reduced depth of the girder, or to the lengths *ab* and *ac*, and consequently the adjusted bending moment diagram must pass through the new point *e*. Repeating this operation at a number of other sections will give a series of new points through which the complete adjusted diagram can be drawn.

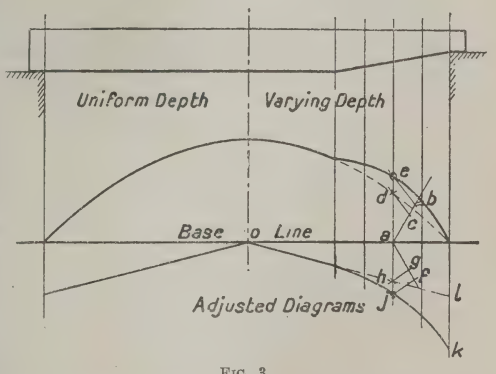

FIG. 3.

Similarly if the shear diagram is to be used for determining the thickness of web plate required, *its depth must first be increased in proportion to the reduction in depth of the girder*, since the sectional area of the web plate is directly proportionate to its depth. Graphically the same operation as above explained can be followed, marking off on the line *af* the lengths *aj* and *ag* equal to the centre and reduced depths of the girder, drawing the lines *gh* and *fj* parallel to one another, and deepening the diagram at this section line to the point *j*. The complete adjusted diagram would take the form of the curved line *ojk*.

In determining the stresses on the several members of a lattice girder such as that outlined

in fig. 4, it is assumed that at the junctions between the several members the connections will allow of free movement, as if pin jointed ; thus the flanges are assumed as hinged at each junction with the lattices, and no allowance is made for the stiffness due to their being actually formed in one piece.

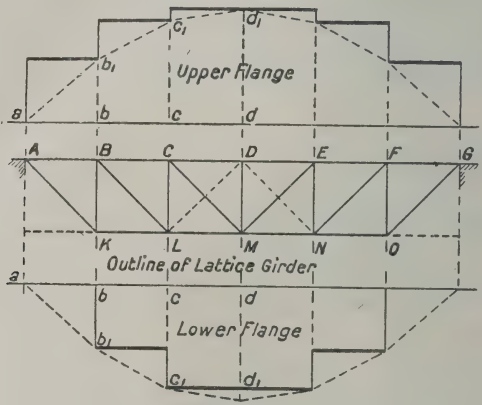

FIG. 4.

This girder rests on abutments at its ends AG, and is loaded at the points BCDEF, say by means of cross girders resting on and fixed to the top flange.

Considering first the load at centre point D, the upper flange does not support it, but the load passes downwards through the vertical strut DM, and is carried by the two inclined ties MC, ME. At the upper ends of these ties the tension due to load at D becomes resolved into compression stress between CE in top flange and compression stress in CL and EN, to which latter stresses must be added a further compression due to loads at points C and E. This transfer of stress is continued to the ends of the girder A and G, the final compression stresses at each end being equal to half the total load, and acting on the bearings at the abutments.

The dotted lines on upper and lower diagrams indicate the bending moment diagrams, and the full lines touching the same show the adjustments necessary owing to the breaking up of flanges and web into a series of members jointed together. The above referred to adjustment is made as follows :—The bending moment diagrams are divided up into sections to correspond with the number of bays in the girder, and as the stress in any section of top or bottom flange must be uniform from joint to joint, the several lines in the diagrams representing the stresses must be parallel to the base line of the diagram throughout the lengths between the joints or junctions between flanges and lattices, all variations in stress taking place suddenly, and being represented by vertical lines in diagram. The stress in the portion AB of upper flange is determined from the moment at point B, and is equal to *bb* ; at BC it is equal to *cc* ; and at centre portion CDE it is equal to *dd*. Similarly in the lower flange, since the girder is complete without any members extending from K or O to the abutments (as dotted lines), the first stressed bar in lower flange is KL, the amount of stress being determined from height *bb* ; the centre portion LMN having its stress determined by the height *cc* ; the stress in the two inclined members CM and EM being equal—on the assumption of equal loads at all upper flange joints—must balance one another, and consequently do not affect the lower flange stress at centre.

Influence Value Tables.

It has already been pointed out on page 288 that the severa lbending moment diagrams given on pages 292 and 293 may be combined to produce one diagram for a series of different loadings.

The same result may be readily obtained, particularly where the value at one particular section is desired, by calculating the bending moment value at that section for each loading, and adding the several values together. This process can be much simplified by the use of the tables on pages 294–296, where the value is given of the effect or influence at a series of other points or sections throughout the length of the beam, of a concentrated load applied at certain points. These values are for a load of unit value for a beam of unit length, and for a beam with free ends, with one end fixed, and with both ends fixed ; end reactions and inflection points are also noted. The brief notes accompanying the tables will explain their application.

INTERNAL STRESSES.

The tendency of a beam to shear, or to deflect, under any system of loading, is opposed by the resistance of the material of which the beam is composed to shearing, or to tension or compression.

It is the general practice to consider the flanges as resisting the bending moment stresses, the web providing the required shear resistance only.

Considering in the first instance the flange stresses, it is evident, if failure is not to occur, that the moment of resistance at all points in every beam or girder must oppose and balance the bending moment there; this resistance moment is the sum of the moments of all the fibre resistances reckoned about the neutral axis. In a beam of ordinary section the resisting fibres lie at various distances from the neutral axis (owing to the thickness of the flanges); but the simplest case is that of a girder with flanges whose thickness is small in comparison to the depth of the girder, so that without material error all the fibres of one flange may be considered to be practically at one distance from the neutral axis. Thus if d = vertical depth of girder between centres of gravity of the two flanges, M= bending moment due to the external loads, we have the general formula,

$$\pm P = \frac{M}{d} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

P being the horizontal stress in either of the two flanges, being compressive stress in the one and tensile stress in the other.

Where the flanges of a girder are of considerable thickness in comparison with the depth of the girder, or the beam is of a non-symmetrical or irregular cross-section, the fibres of either flange cannot be considered as practically at one distance from the neutral axis, and it is necessary to take into account the varying distances of the fibres from the neutral axis, in the following manner:—

Under the action of any transverse bending, the intensity of the tensile and compressive stresses varies in different fibres of the beam, being greatest in the extreme fibres at the top and the bottom of the cross-section, while the fibre-stress will be zero at the 'neutral axis.'

Whatever may be the figure of the beam's cross-section, the neutral axis will be a horizontal line drawn through its centre of gravity; and the intensity of the stress in any fibre will be proportional to the vertical distance y of the fibre above or below the neutral axis.

If a denotes the sectional area of any thin layer of fibres lying at the height y above the axis, the total stress in that layer will be proportional to ay, and its moment about the neutral axis will be proportional to $ay \times y = ay^2$. The summation of the quantities ay^2 for the different layers is the so-called 'moment of inertia' of the beam, or

$$I = \Sigma (ay^2) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

When the bending moment, M, due to the external forces has been found in the manner already described, the problem will often be to find the maximum stress per square inch, f, in the extreme layer of fibres; and if y denotes the vertical distance of that layer from the neutral axis, we have

$$f = \frac{My}{I} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

Where the section of the beam is symmetrical about the neutral axis, as in rolled joists, y=half the vertical depth of the beam between centres of gravity of the two flanges, or $\frac{1}{2}d$, and for such sections the above formula may be written,

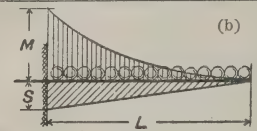
$$f = \frac{Md}{2I} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

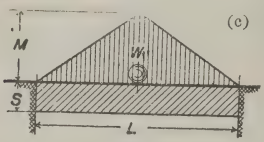
In the case of cast iron, whose strength in compression is much greater than in tension, the tension flange should be made considerably larger than the compression flange. In rolled steel joists the two flanges are made of equal area, and an approximate value for the moment of resistance may be readily found by adding to the actual area of each flange $\frac{1}{6}$th of the area of the web, and then reckoning the depth d as the depth between the centres of gravity of the two flanges; then with A = area of one flange and $\frac{1}{6}$th web, and F = max. safe stress on steel,

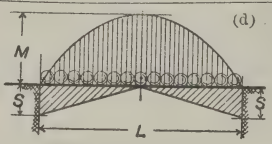
$$\text{Approx. resistance moment} = A \times F \times d \quad . \quad . \quad . \quad . \quad (7)$$

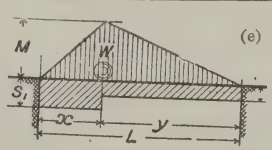
When the thickness of the web is small in comparison with the width of the flanges, the extreme tensile stress, f, under the breaking load, as determined by formula (5) corresponds nearly with the ultimate tensile strength of the material; but should the girder have a very substantial web, or should the section be that of a solid rectangle, the calculated breaking load will generally be found to be lower than the actual breaking load. For such cases see formula on page 298.

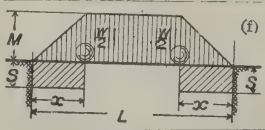
TABLE I.—BENDING MOMENTS, SHEARING STRESSES, AND DEFLECTION OF STEEL GIRDERS. Graphic Diagrams and Formulæ.

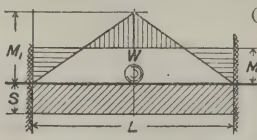


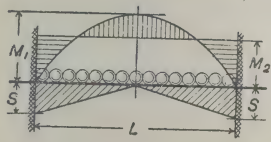


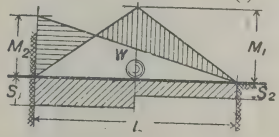


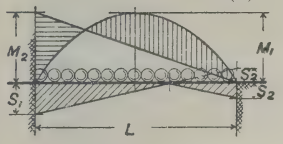


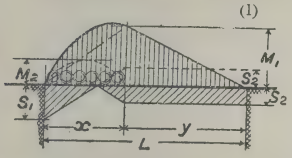


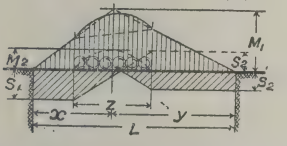












Type.	Formulæ. Bending Moment.	Shearing Stress.	Maximum Deflection.
(a) 	$M = WL$	$S = W$	$\frac{WL^3}{3EI}$
(b) 	$M = \frac{WL}{2}$	$S = W$	$\frac{WL^3}{8EI}$
(c) 	$M = \frac{WL}{4}$	$S = \frac{W}{2}$	$\frac{WL^3}{48EI}$
(d) 	$M = \frac{WL}{8}$	$S = \frac{W}{2}$	$\frac{WL^3}{76{\cdot}8EI}$
(e) 	$M = \frac{Wxy}{L}$	$S_1 = \frac{Wy}{L}$ $S_2 = \frac{Wx}{L}$	$\frac{Wxy(2L-x)}{27EIL} \times \sqrt{3x(2L-x)}$
(f) 	$M = \frac{Wx}{2}$	$S = \frac{W}{2}$	$\frac{Wx(3L^2-4x^2)}{48EI}$
(g) 	$M_1 = \frac{WL}{4}$ $M_2 = \frac{WL}{8}$	$S = \frac{W}{2}$	$\frac{WL^3}{192EI}$

TABLE II.—BENDING MOMENTS, SHEARING STRESSES, AND DEFLECTIONS—*contd.*

Type.	Formulæ. Bending Moment.	Shearing Stress.	Maximum Deflection.

These tables are calculated for a unit load, and for a girder of unit length ; the length of the girder is divided into 20 equal sections, and the bending moment values are given at each section point for unit load placed on each section line in turn. For any weight and any length of span it is necessary only to multiply the proper tabular coefficient by the number of units in the load and in the span to obtain the actual

TABLE IV.—INFLUENCE VALUES

BEAM FIXED AT RIGHT END.

Load at Section.	Bending Moment Coefficient at Sections noted—(To left of heavy broken line—positive moments; to right—negative).																			Left end reaction.	Right end reaction.	Inflection point.

bending moment value desired. Thus for a load of 2 tons on a girder of 20 feet span the tabular values multiplied by 2 × 20 will give the actual values in foot-tons.

Taking the above load and span, and a free-ended girder, with load at ¼th span (or line ·25) the bending moment under the load and at centre of span will be respectively (·187 × 2 × 20) 7·48 and (·125 × 2 × 20) 5 foot-tons respectively. For a girder fixed at one end the corresponding values will be (·158 × 2 × 20) 6·32 and (·066 × 2 × 20) 2·64 foot-tons respectively.

In some cases the values are only approximate, since the tabular values give 3 decimal figures only; for example, in the first calculation the full tabular value would be ·1875, and the accurate result 7·5 foot-tons. The values for a load distributed over a part or the whole of the span may be obtained approximately by assuming the total load as formed of a number of equal loads placed at adjoining section points; the result here would generally be near enough to the true value for all practical purposes.

TABLE VI.—MOMENTS OF INERTIA, SECTIONAL AREA, ETC., FOR VARIOUS SIMPLE SECTIONS.

Section.	Area.	Neutral Axis.	Moment of Inertia.
 (a)	$\frac{\pi D^2}{4}$ $\pi = 3{\cdot}1416$	Through centre	$\frac{\pi D^4}{64}$
 (b)	$\frac{\pi(D^2 - d^2)}{4}$	Through centre	$\frac{\pi (D^4 - d^4)}{64}$
 (c)	D^2	Through centre	$\frac{D^4}{12}$
 (d)	D^2	Through centre $y = \frac{D}{1{\cdot}4142}$	$\frac{D^4}{12}$
 (e)	BD	Through centre	$\frac{BD^3}{12}$
 (f)	$BD - bd$	Through centre, parallel to B Through centre, parallel to D	$\frac{BD^3 - bd^3}{12}$ $\frac{DB^3 - db^3}{12}$
 (g)	$\frac{BD}{2}$	$y = \frac{2}{3}D$ Through Base Line, through Apex, and parallel to Base	$\frac{BD^3}{36}$ $\frac{BD^3}{4}$ $\frac{BD^3}{12}$
 (h)	$B(D - d)$	Through centre and parallel to B	$\frac{B(D^3 - d^3)}{12}$

The value for the moment of inertia for the standard steel sections of rolled joists, angles, tees, etc., can be got from the section books issued by many of the rolling-mill companies and constructional engineering contracting firms.

The value for the moment of inertia about any other axis parallel to and at a distance y from the neutral axis $= I$ for neutral axis $+$ (area $\times y^2$) . . . . . (8)

The value for the radius of gyration (see page 299, etc.) is $R = \sqrt{\frac{I}{\text{Area}}}$. (9)

Solid Rectangular Beams.

Where the strength can be shown to vary directly as the breadth of the beam and as the square of the depth, it is better, for the reason given above, to calculate the strength by means of coefficients derived from direct experiments in cross-breaking ; thus

$$\text{Breaking load in tons} = \frac{\text{Breadth in inches} \times \text{depth in inches}^2}{\text{Span in inches}} \times c \times k \quad . \quad . \quad (10)$$

TABLE VII.

Material	Coeff. c.	Ends of Beams.	Coeff. k.
Mild Steel	3·50	One fixed, other end loaded	1
Cast Iron	2·30	,, ,, load distributed	2
Fir (Spruce)	0·60	Both supported, load in centre	4
English Oak	0·75	,, ,, ,, distributed	8
Red Pine	0·65	Both fixed, ,, in centre	6
Yellow Pine	0·50	,, ,, ,, distributed	12
Pitch Pine	0·75		

The factor of safety for steel may be $\frac{1}{4}$th to $\frac{1}{3}$th breaking load ; for the other materials it may vary between $\frac{1}{5}$th and $\frac{1}{7}$th breaking load. If the beam carries a heavy live load the safe load should be further reduced.

Factor of Safety.

The safe working stress is usually taken as some fraction of the ultimate strength of the material ; it requires careful consideration and much experience to decide on the correct value for this fraction. This consideration is further complicated when any portion of the total load is such that it is applied and removed, since these conditions may produce a considerable dynamic effect. Another point which must be kept in view is that the maximum stress, however produced, must be well within the elastic limit of the material, so as to avoid any permanent distortion or set. For mild steel such as is used in general structural work, the ultimate strength will vary from 27 to 32 tons per square inch, with an elastic limit of 14 tons per square inch and upwards : the maximum stress should therefore not exceed 9 to 10 tons per square inch, or say a factor of safety of 3 with respect to the ultimate strength.

Repeated or fluctuating loads.—These can be classed under two heads, first where the load is such as will produce stresses in the structure varying from zero to a maximum ; and second where the load will produce stresses varying from compression to an equal tension.

Wöhler's law of stresses for repeated loading and reversed loading may be briefly indicated thus :—

Class 1.—Static or dead loading	ratio	3
,, 2.—Loads producing stresses varying from zero to maximum . .	,,	2
,, 3.— ,, ,, ,, ,, ,, comp. to equal tension .	,,	1

As the load carried by any structure is always composed partly of dead and partly of live or fluctuating loads, difficulties arise in determining the stresses in the several members of the structure, for the following reasons. The weight of the structure itself provides a necessary dead load, irrespective of any other additional dead load (for example, water flowing into a tank, although actually a live load, is so steadily added to the structure as to be *practically* a dead load), and it is obvious that the dynamic resistance of this dead load must more or less reduce the actual dynamic effect on the structure of any live load. A simple formula has been suggested by Mr. E. H. Stone, M.Inst.C.E., which he calls his ' Range ' formula, and which takes into account the *immediate effect* (due to sudden loading, as when a train passes over a bridge), and the *cumulative effect* (that produced in time by repeated loading and unloading). The former effect, as compared with that due to the same amount of dead load, was deduced from experiments, while the second effect was deduced from Wöhler's experiments : these two effects were then combined in a rational manner to give the total effect of the moving load, as compared with that of an equivalent amount of dead load. Starting with a maximum safe stress for *dead loads alone* of 9 tons per sq. in. for mild steel, Mr. Stone deduced the following formula for obtaining the equivalent dead load stresses for varying percentages of life to dead loads, which would produce an actual maximum stress of 9 tons per sq. in. (p = percentage of live to dead load).

$$\text{Safe working stress} = 9 - (5 \times p) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (11)$$

The following table is based on this formula :—

TABLE VIII.—DEAD LOAD EQUIVALENTS FOR COMBINED LIVE AND DEAD LOADS.

p	E.D.L.	p	E.D.L.	p	E.D.L.
100	4·00	65	6·89	30	8·55
95	4·49	60	7·20	25	8·69
90	4·95	55	7·49	20	8·80
85	5·39	50	7·75	15	8·89
80	5·80	45	7·99	10	8·95
75	6·19	40	8·20	5	8·99
70	6·55	35	8·39	0	9·00

p = percentage of live load in total load. E.D.L. = equivalent dead load stress.

Deflection of Beams.

Deflection formulæ for various arrangements of loading are given in tables 1 and 2, pages 292 and 293. For structural steel the value of E (the modulus of elasticity) may be taken at 30,000,000 lbs. and the value of W must then be expressed in lbs. also. For the value of E for other materials see page 263.

COLUMNS AND STRUTS.

The strength of columns or struts depend not only on the cross-sectional area of the member, but also on its height or length, and on the condition of fixture of the ends. As the ratio of the length to the least diameter increases, the column becomes more *slim* or liable to fail by bending under its load ; such a ratio might thus be called the *ratio of stiffness or slenderness* of a column, and so that this ratio may be used as a means of comparing the strength or stiffness for columns of varying cross-section, the value for the radius of gyration (see p. 297) of the cross-section should be adopted instead of the diameter, since it is obvious, for example, that the diameters of a square and a round column may be the same, but the stiffness would be quite different.

The ends of columns are divided into three classes or conditions of fixture :—

1. Both ends hinged, or free to move.
2. One end hinged and one end fixed.
3. Both ends fixed.

The limiting values for $\frac{L}{R}$ in the tables on pp. 300, 301 have been taken as 200, and this should very rarely be exceeded, owing to the practical difficulties in producing a perfectly straight long column, and one free from internal stresses ; and also of erecting such a column on rigid foundations, and ensuring a truly central loading.

The formulæ adopted in calculating tables are given under the same.

Eccentric Loads.

Where the load is not applied centrally, as where a beam rests on a bracket attached to a column, considerably increased stresses may arise through the bending tendency introduced.

The equivalent concentric load which would produce the same maximum stress as that due to the actual eccentric load may be found as follows :—

$$\text{EQUIVALENT CONCENTRIC LOAD} = W\left(1 + \frac{xy}{R^2}\right) \quad . \quad . \quad . \quad . \quad . \quad (12)$$

where W = Eccentric load.

x = Distance from neutral axis of stanchion to point of application of load = eccentricity

y = Distance from neutral axis to edge of stanchion nearest load.

R = Radius of gyration of cross section of stanchion about neutral axis at right angles to line of eccentricity

TABLE IX.—MILD STEEL STANCHIONS.

Maximum Safe Stresses per sq. in. of Section. (London Building Act Amendment, 1909.)

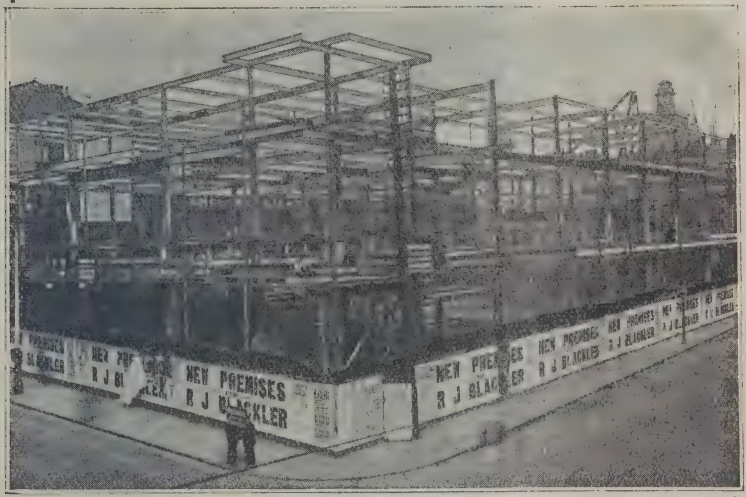
A = Both ends hinged.
B = One end hinged, one end fixed.
C = Both ends fixed.

The above table gives an extension of the empirical working or safe stress values adopted by the London County Council, and embodied in their (General Powers) Act 1909. This table should be used for all districts where the L.C.C. Building Regulations are enforced.

The limit of height of a stanchion should, as a rule, not exceed the lesser of the two following values :—

1. 160 times the least radius of gyration.

2. 40 times the least overall depth or breadth of the section.



The economical ratio of slenderness for the three types of stanchions, namely the point beyond which the section increases at a greater rate than below this point, occurs at 100, 140, and 160. Below these values the rate varies one ton per sq. in. for each variation of 40 in the $\frac{L}{R}$ values ; above these values the rate of change is two tons, being double

A = Both ends hinged.
B = One end hinged, one end fixed.
C = Both ends fixed.

The following are the formulæ used in calculating the above table:—

$$\text{Breaking strength in tons per square inch} = \frac{F + f - \sqrt{(F+f)^2 - 2{\cdot}4\,Ff}}{1{\cdot}2} \quad . \quad . \quad (13)$$

= Ultimate compressive strength = 26 tons per square inch in this table.

$$F = \begin{cases} E\pi^2 \times \left(\frac{R}{{\cdot}6L}\right)^2 \text{ for both ends fixed.} \\ E\pi^2 \times \left(\frac{R}{{\cdot}8L}\right)^2 \text{ for one end hinged, one end fixed.} \\ E\pi^2 \times \left(\frac{R}{L}\right)^2 \text{ for both ends hinged,} \end{cases}$$

E = Modulus of elasticity = 12,000 tons.
π = 3·1416.
R = Minimum radius of gyration of cross section.
L = Height of stanchion in inches.

Riveted Joints in Girderwork.

The riveted joint of a tension-member may fail either by the tearing of the plate, or the shearing of the rivets, or in some special cases by the crippling of the bearing area between plate and shank of rivet.

The tearing of the plates is resisted by the tensile strength of the plate per square inch of area taken over the *net effective section* between rivet holes. When the assumed line of fracture is at right angles to the direction of the pull, the sectional area measured on this line between the rivet-holes is the net effective section. But when the line of fracture may follow a zigzag or inclined direction, the effective sectional area should be taken at about three-fourths of the area measured on such a line. The fraction is not universally applicable, but will generally meet the case of ordinary zigzag riveting.

The shearing of the rivets is resisted by the shearing strength of the rivet-material per square inch of area taken over the effective section of the rivets engaged. Assuming all the rivets to take an equal share in the work, the number of rivets engaged in resisting the total pull upon the tie will be the whole number of rivets in the case of a lap-joint such as that shown in figs. 7 and 8 ; while in the case of a butt joint, such as No. 2 of fig. 9, it will consist only of the rivets employed on either side of the joint. But in any large assemblage of rivets allowance should be made for unequal distribution of the work when calculating the number of rivets required for a joint.

For rivets in ' single shear,' as in the case of lap joints, and in butt joints covered by a single cover-plate, the effective section of each rivet is simply the area of its cross-section. But wherever practicable double cover-plates should be employed, placing the rivets in ' double shear,' and in this case the effective section of each rivet should be reckoned at $1\frac{3}{4}$ times the sectional area of the rivet.

In wrought-iron work the shearing strength of good rivet iron per square inch is fully equal to the tensile strength of the plates ; and the effective rivet section is often made equal to the effective plate section, an allowance of 10 per cent. being sometimes added in the case of large joints.

The shearing strength of steel rivets may be taken at 24 tons per square inch, while the plates have often a tensile strength of 26 to 32 tons ; and the rivet section will generally require to be somewhat greater than the plate section.

The ' efficiency ' of a riveted joint is the ratio between its strength at the weakest part and the strength of the unperforated plate.

RIVETING.

Rivets.

The heads (fig. 5) are usually either snap or pan. Snap heads are used generally in machine riveting. The points are countersunk, conical, or snap ; the former are largely employed in iron shipbuilding, where a flush surface is required, the latter in ordinary boiler and bridge work. Conical, also called *staff* or *hammered*, points are chiefly used where the restricted space only allows of hammering.

The following figures give ordinary proportions of rivet heads in terms of diameter of shank.

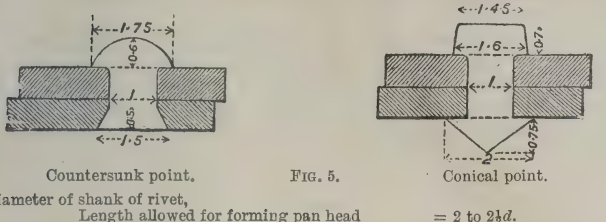

Fig. 5.

If d = diameter of shank of rivet,

Length allowed for forming pan head = 2 to $2\frac{1}{2}d$.
" " " snap head = $1\frac{1}{2}d$.
" " " countersunk head = $1d$.
" " " conical head = $1\frac{1}{2}d$.

When a conical form is given under the rivet head an additional length of about $\frac{1}{4}''$ is usually allowed in making the rivet.

Diameter of Rivets or Rivet Holes.

d = diameter of rivet hole ; t = thickness of thickest plate.

Fairbairn's Rule, commonly used { When t is less than $\frac{1}{2}''$, $d = 2t$. / When t is equal to, or greater than, $\frac{1}{2}''$, $d = 1\frac{1}{4}t$.

With rivets so proportioned the total number in single shear, such as lap, single cover and grouped, joints will, when the resistance to shearing is taken at 4 tons and bearing at 5 tons, depend on the number required for shearing, in $\frac{1}{2}''$ plates and over $\frac{1}{2}''$, and for bearing with plates under $\frac{1}{2}''$ thick.

When more than 2 plates, besides the covers, are riveted together, as in flanges of girders, some engineers add $\frac{1}{16}''$ to d for each extra plate.

Unwin's Rule for Rivets.—$d = 1{\cdot}2\sqrt{t}$.

Rivets of more than $1\frac{1}{8}''$ diameter are rarely used.

The rivet holes are made about $\frac{1}{16}''$ larger than the rivets, to allow for expansion when heated. For ordinary work the proportions of diameter of punch to that of bolster hole in the die varies from 1 : 1·15 to 1 : 1·2 ; the greater the difference, the less cleanly cut will the burr be, but the metal round the hole will be stronger, being less reduced and more compressed. The hole when punched is slightly conical.

It is hardly practicable to temper a punch so as to punch a great number of holes if it is of less diameter than the thickness of the plate, or even with a diameter of equal thickness. Punched holes should never be less than $1\frac{1}{2}$ diameter apart or from edge of plate. For drilled holes the limit may be 1 diameter.

Pitch of rivets = distance from centre to centre of rivet. *Longitudinal pitch* = pitch in direction of stress. *Transverse pitch* = pitch at right angles to stress. *Zigzag pitch* = minimum pitch when placed zigzag ; this should slightly exceed the transverse pitch. *A pitch line* is a straight line running through the centres of a longitudinal or transverse row.

Minimum pitch = $2\frac{1}{2}$ diameters for punched or 2 for drilled holes.

Maximum longitudinal pitch in compression plates = 12 times thickness of weakest outside plate.

BRIDGE RIVETS.

In plate girders the plates are from $\frac{1}{2}''$ to $\frac{1}{2}''$ thick, with rivets $\frac{3}{4}''$ to $1''$ diameter ; usually $4''$ pitch in the top of the girder, $5''$ in the bottom.

Strength of Rivets and Plates.

Mean tensile breaking strength of best rivet iron, such as BBB Staffordshire, best Yorkshire or Lowmoor (and the best only should be used), is from 26·33 tons per square inch (Fairbairn) to 25·98 tons per square inch (Kirkaldy); whilst the contraction of fractured area should not be less than 40 per cent.

Forge Tests for Rivets.—When *cold* they should stand being hammered double, or being upset endways, a $\frac{3}{4}''$ rivet $2\frac{1}{2}''$ long being hammered down to a cylinder $1''$ long, without any sign of cracking. A rivet ready heated for use should now and then be taken, allowed to cool, and treated as above, to see if they are being overheated. Much overheating is detected by the burnt, scaly appearance of the surface of shank ; $\frac{3}{4}''$ or even $1''$ rivets should not be over 20 minutes in the fire. When *hot* the heads should stand hammering down to less than $\frac{1}{8}''$ thick without cracking at edges ; and the stalks should stand having a punch, even more than their own diameter, driven through them without cracking round the hole.

The above tests are equally applicable to steel rivets.

Careful punching does not injure soft plates, but weakens hard or steely iron plates from 15 to 30 per cent.

Sharp edges of drilled holes reduce the shearing resistance of rivets, but rounding the edges of the holes increases resistance of rivet.

Drilled rivet holes reduce the strength of a plate by 1½ per cent., and punched holes about 9 per cent. Punching and counter-sinking reduce the strength 4 per cent., but if the holes are punched, reamered, and countersunk, there is little reduction in the strength of the plate. Comparative tests of high tensile plates, connected by iron and by high tensile rivets, show that ½-in. iron rivets worked cold in single shear have a shearing strength of 3·6 tons compared with 6·6 in the case of high-tensile steel worked cold, and 9·2 in case of the same steel worked hot. For double shear the same figures are 6·6, 13·1, and 18·4. Experiments show that the bearing pressure with high tensile steel rivets does not exceed 60 lbs. per square inch.

(*Sir P. Watts.*)

Riveting.

Riveting gangs consist of a holder-up, two riveters, and one or two boys for heating and supplying rivets. Rivets are heated in a portable hearth or a reverberatory furnace. Before inserting the rivet the plates round the hole should be hammered into positive contact, and the holes ascertained to be concentric.

Riveting hammers vary from 2 to 7 lbs., the holding-up hammer or 'dolly' from 10 to 40 lbs. 130 to 150 rivets is a day's work of 13 hours of a riveting gang. 360 to 720 can be put in by a riveting machine.

Riveted Joints.

The loss of strength is ordinarily, for chain-riveted joints (fig. 6), 15 per cent.; for double-riveted, 30 per cent.; for single-riveted joints, 44 per cent., as compared with the strength of the plate unpunched.

FIG. 6. Grouped Butt Joint. Chain Riveting.

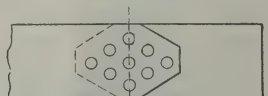

FIG. 7. Lap Joint. Lozenge Riveting.

Zigzag Riveting.—In this (fig. 8) the distance between the transverse pitch lines should be at least two-thirds the transverse pitch of the rivets.

Lozenge Riveting.—Arranging the rivets in this way, as illustrated by the lap-joint of fig. 7, and calculating the plate strength and rivet strength at each of the possible lines of fracture, it is possible to obtain a strength of joint equal to the strength of the whole plate less one rivet hole. With the same efficiency a still better joint for a plate-tie may be made with two cover-plates of lozenge form, the maximum row of rivets being repeated on each side of the butt joint.

Cover-Plates.—In the special case last mentioned the united thickness of the cover-plates will have to be considerably greater than that of the main tie, and will be determined by the net section of cover taken through the maximum row of rivets. In chain riveting generally it would be theoretically sufficient to make the united cover thickness equal to the plate thickness, but in practice it is often made somewhat greater, both in single and double covers. If there is

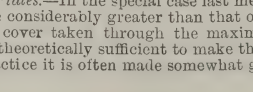

FIG. 8. Lap Joint. Zigzag Riveting.

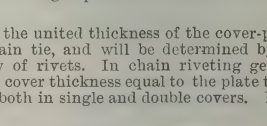

FIG. 9.

a whole plate on one side, as in No. 1, fig. 9, a single cover-plate may be used on the other side equal in thickness to the jointed plate. When the member consists of several thicknesses of plate, as in No. 3, they may with advantage be all jointed between one pair of cover-plates, arranging the several layers to break joint one with another, and leaving between every two joints a space containing a sufficient number of rivets to take up the pull of one layer of plates.

Rolling Load on Railway Bridges.

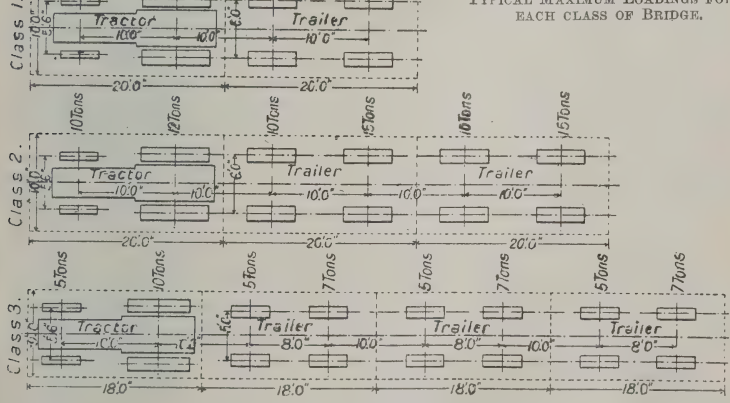
The effective weight of the rolling load, per foot lineal of each line of way, will depend upon the width of span. The heaviest train would consist of locomotives coupled closely together, but while a bridge of short span might frequently be covered by such a train, or by the two engines that often head the train, a bridge of very long span would never be subjected to such a load per foot lineal over its entire length. But for spans shorter than the length of one engine, the load may be very much greater than the weight of the engine per foot of its extreme length. Taking the worst position of the wheel-loads, and the heaviest class of engines now in use upon English lines of railway, the equivalent distributed load per foot lineal may be estimated as follows :—

For spans of 10 feet, a load of 4·40 tons per foot.						For spans of 100 feet, a load of 2·07 tons per foot.					
„	20	„	„	3·25	„	„	„	150	„	„	2·00	„	„
„	30	„	„	2·88	„	„	„	200	„	„	1·90	„	„
„	60	„	„	2·30	„	„	„	300	„	„	1·75	„	„

In designing cross girders the maximum axle load is taken at 22 tons.

These loads are exclusive of any allowance for impact, which is generally allowed for by varying the unit stress per sq. in. to suit the application of the load :—From 4·5 tons per sq. in. for cross girders to 6·5 tons per sq. in. for main girders 100 feet span and over. The loads given are considered to be the maximum that can be obtained from the present loading gauge of British railways.

Loads on Highway Bridges.*



The following three classes of bridge loading should give suitable provision for all forms of traffic and loading.

Class 1.—Bridges on main thoroughfares in great industrial centres, and within a radius of 25 miles thereof. Will take ordinary boiler trollies and heavy guns.

Class 2.—Bridges on secondary roads in great industrial centres, and on main roads outside a radius of 25 miles. Will take 20-ton rollers, large traction engines, large ploughing engines, L.C.C tramcars, etc.

Class 3.—Bridges on provincial roads other than main roads. Will take 15-ton rollers, ordinary traction engines, ploughing engines, brick trucks, and siege guns.

Note.—For certain localities, as Leeds, Sheffield, West Bromwich, Salford, etc., a maximum axle load of 35 tons, or a gross load of 70 tons on two axles, with a wheel base of 10 × 6 eet should be provided for.

TYPICAL MAXIMUM LOADINGS FOR EACH CLASS OF BRIDGE.

FIG. 10.

* For further particulars see Joint Committee's Report on Loads on Highway Bridges, published by the Concrete Institute.

Only one of the above loads to be on the bridge at one time.

All loads are axle loads, i.e. on two wheels.

In addition to the above passing loads, 1 cwt. per foot super should be provided for over the part of the bridge not occupied by these loads.

In designing bridges with cross girders, the latter must be sufficient to carry the maximum axle load travelling across the centre of their spans at the given wheel base, in addition to the dead load, and distributed load of 1 cwt. per foot.

In designing arched bridges, the curve of thrust should be drawn when the heaviest axle has reached the centre of the nearest haunch, and again when it has reached the centre of the further haunch ; a further condition, when it has reached the centre of the bridge, should also be taken.

The distribution of point loads through the thickness of the road material may be taken as equal to the depth (i.e. the angle of dispersion can be taken as 45°).

To allow for the virtual increase in the value or intensity of a rolling load by vibration due to irregularities in the road surface, etc., it is suggested that a factor of safety of 4 for spans over 50 feet, and 5 for smaller spans be adopted.

STEEL ROOF FRAMING AND COVERING.

Some points to be considered in designing steel roofing :—

(a) *Nature of Covering.*—If of **corrugated sheeting,** either ridged or curved type may be adopted ; in the latter the joints near crown of roof lie nearly horizontal, and leakage through rain being blown in must not be overlooked. A continuous covering, such as tarred felt or asphalt laid on timber boarding, is applicable to ridged or curved types.

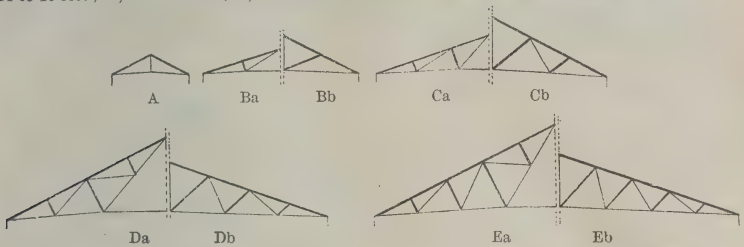
With slates or tiles, the ridged type (except in very large spans) is necessary.

(b) *Rise of Roof.*—Where this is not controlled by architectural requirements, a rise of about $\frac{1}{5}$ span will generally prove most economical. Where water-tightness is essential, $\frac{1}{4}$ rise may be adopted ; a rise of even $\frac{1}{3}$ may be used with slates or tiles. In very exposed positions a low rise of $\frac{1}{8}$ has been provided, but here leakage is likely to prove troublesome.

(c) *Lighting and Ventilation in Roof.*—Skylights can be arranged in any position on the slope of a ridged roof, or set low down on curved roofs. Lights are often combined with ventilators at the centre or ridge of the roof. Ventilation at the ridge may consist merely in slightly raising the ridge cap above the sheets ; by the use of special ridge sheeting (often curved) supported on raised purlins ; or where greater ventilation is desired, the cover may be raised to a considerable height and louvres provided for weather-tightness. See sketch examples.

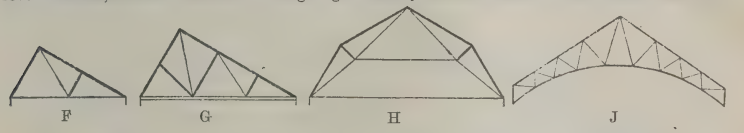
(d) *Temporary Structures.*—Here the framing and covering can be designed as light as possible, and factor of safety reduced to about 3, since allowance for rusting and general deterioration need not be considered. The self-supporting type of curved roof should be considered in this case.

(e) *Special Headroom* generally requires a special type, as the main tie cannot economically be raised much over $\frac{1}{10}$ rise for ridged or curved trusses of ordinary design. Two suggestions are given in sketch examples to meet this requirement.



Struts, or members in compression, should be kept as short in length as possible. The strength of *ties* to resist tension is independent of their length, and no consideration on this point is necessary, except that relating to the carrying of their own weight.

The Purlins (or horizontal bearers which carry the weight of the roof covering, and the wind and snow load on the same, and transmit these loads to the roof trussing) should rest, wherever possible, on the rafters close to the points where the struts and ties meet, and stiffen the same ; loads applied between these junction points (usually termed 'joints') may induce considerable *bending stresses* which must be carefully allowed for, generally at considerable expense, owing to the large increase in section which may be necessary.



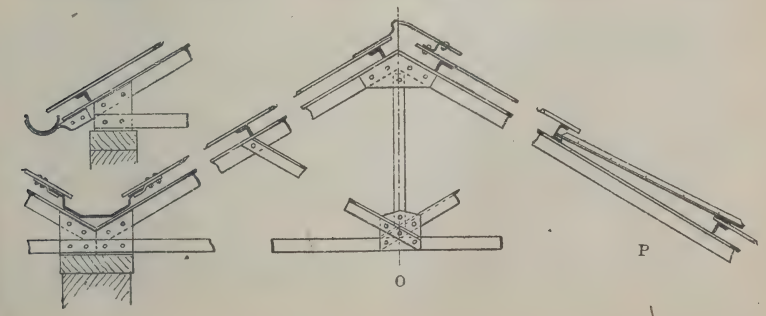
The unsupported length of the Rafter, that is to say the length between the joints, should not exceed 7 to 8 feet where the purlins are fixed close to the joints ; where purlins occur between the joints, this length should be considerably reduced, or the section of the rafter increased to resist the bending stresses.

In the brief notes accompanying the outline types of roofs shown here, the application of some of the preceding hints will be evident.

For ordinary conditions the types shown below are suitable up to the following spans :—A, 14 to 16 feet; B, 25 to 30 feet; C, 45 to 50 feet; D, 55 to 60 feet; and E, 70 to 80 feet.

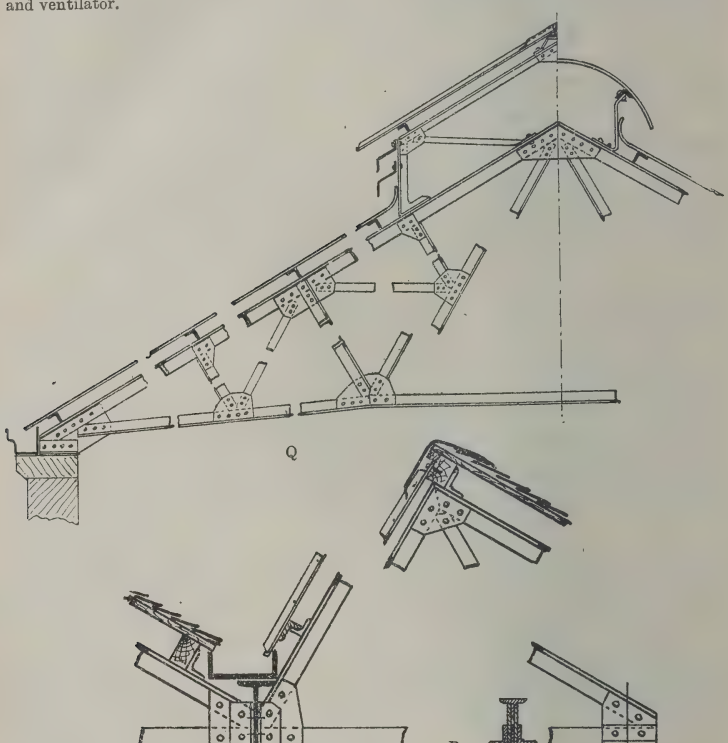
The two rises indicated in B to E are $\frac{1}{4}$ span and $\frac{1}{3}$ span. Where special conditions do not arise, the form of bracing should be decided by considerations of length and inclination of the several struts, and convenience for designing efficient junctions between the struts and ties.

Types of ridged roofs designed to provide special lighting, such as is required in spinning and weaving factories, are shown in F and G; the long slope is covered with sheets or slates, and the short, upright slope glazed and turned towards the north, thereby ensuring efficient light free from direct sunshine. These types are frequently called 'Saw Tooth' or 'Northern Light' roofs, and are suitable for spans of 18 to 20 ft., and 25 to 30 ft. respectively.



Types H and J show a high rise, with main tie raised to give increased headroom; the former may frequently be adopted for factories, the lower slopes being glazed and the upper slopes sheeted or slated.

The curved types K, L, and M, are similar to A, B, and C, but arranged for a curved sheet covering, and may be adopted for similar spans.



Types N are in reality curved lattice girders, and may be designed for large spans such as are required for markets, railway stations, public halls, or the like.

Sketch Details.—Sketch O suggests details for a ridged roof, type Bb; on left two spans meet and a valley gutter is provided, and above this a sketch of an eaves gutter. At the apex, or

ridge, an ordinary ridge cap is shown on the left, and on the right a plain ridge cap is slightly raised on light brackets to provide a small amount of ventilation.

Sketch P indicates a skylight in the slope of a roof. Sketch Q gives suggestions for type Da. At apex a simple ventilator is shown on the right, and a larger louvred ventilator on the left. In the latter arrangement the straight cover may be glazed, thus forming a combined skylight and ventilator.

Q

R

Sketch R is that for a 'Northern Light' roof, types F or G. A valley detail (showing this part supported on a rolled steel beam) with valley gutter is given, also an eaves shoe detail. The long slope is covered with timber and slates, and the short slope is glazed.

Corrugated Sheets and Fixings.

Sheets can be procured in lengths from 5 to 10 feet, and in thicknesses from No. 16 to No. 26 B.W.G.; for special or very temporary purposes, No. 28 B.W.G. might be adopted.

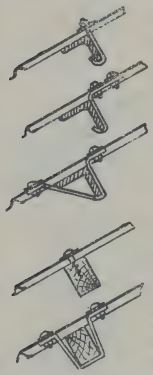
Corrugations from 2 inches width in light sheets to 6 inches in heavy sheets may be got, but for usual conditions the following sizes will meet all requirements:—

5–5 inch corrugated sheets (depth of corrugations 1¼ in.)
6–5 " " " (" " " ⅜ ") See Sketch S.
8–3 " " " (" " ¾ ")
10–3 " " " (" " ")

For ordinary conditions, a side lap of one corrugation (see right-hand of Sketch S) would be adopted, but for special water-tightness or stiffness, two corrugations lap could be given (see left

hand of Sketch S). The effective width of the above sheets would be 25 inches or 30 inches, for single lap, and 20 inches or 25 inches for double lap.

S



In the 3-inch corrugated sheets, the corresponding widths would be 24 and 30 inches for single lap, and 21 and 27 inches for double lap.

The end lap is generally given at 6 inches.

Sheets should be connected together by means of galvanised rivets or bolts and washers: these would be placed about 9 inches apart along the side laps, and at every second corrugation in the end laps, being in all cases placed on *top* of the corrugations to check leakage. For *double* corrugation side lap, place rivets or bolts in edge of outer sheets 6 inches apart, and 12 inches apart in inner corrugation.

Five-inch corrugations should always be adopted for No. 16 B.W.G. sheets, and may be used for No. 18 or 20 B.W.G.; 3-inch corrugations may be used for 18 or 20 B.W.G., and always for No. 22 B.W.G. and upwards.

In very exposed positions, and particularly with light gauge sheets, Wind Ties of flat or light angle section are sometimes carried along the length of the roof, and held in position by means of the purlin bolts. A line of these wind ties near each eaves level will considerably strengthen the roofing; and it is sometimes also desirable to add ties over some of the intermediate horizontal joints in the roof sheets, to further resist excessive winds.

T

U

V

W

X

In addition to connecting the roof sheets together, they must be securely fixed to the roof purlins, and suggestions for doing this are here indicated:—

Sketch T, simple hook bolt, with nut and washer outside, connecting sheets to steel angle purlin.

Sketch U, similar to above, but formed of flat clip bolted to sheets.

Sketch V, a more secure form of flat clip carried round purlin and connected to sheets by bolts and washers at ends.

Sketch W, galvanised nail or wood screw and washer, for simple connection to timber purlin.

Sketch X, flat stirrup carried round timber purlin; generally made with slight clearance in width, to admit of adjustment due to change of temperature in the sheet covering.

The washers used with the bolts are sometimes formed of lead, or of some special form, to check leakage at the bolt holes. Red lead putty, or rope yarn soaked in red lead paint, is sometimes specified to be placed under the nut or washer, but such special treatment is seldom justifiable, or really necessary.

Corrugated Sheets are generally galvanised, but in localities near the sea, or in manufacturing districts near chemical works where acid fumes are likely to be given off, the galvanising quickly disappears, and the sheets become eaten through and spoiled. In such conditions the galvanised sheets should receive two good coats of metallic oxide paint shortly after erection, or plain corrugated sheets used, these being well tarred and sanded after erection, and at such intervals as may be necessary to efficiently protect the sheets from corrosion.

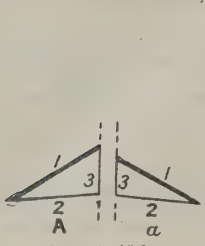
Self-Supporting Roofing.

This term is generally applied to a type of curved roofing in which the curved rafters of the trussing are dispensed with, their place being supplied by the corrugated sheets themselves.

In the smaller spans, say up to 15 to 20 feet, the roof sheets are connected to timber or steel eaves beams, and the bracing (generally as types K or L) bolted direct to the curved roof sheets.

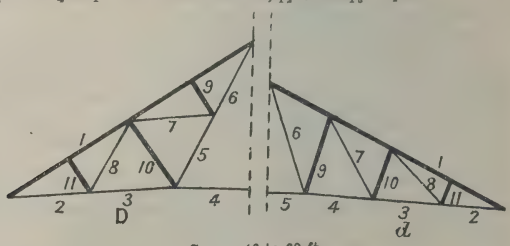
In the larger spans angle purlins are securely clipped to the curved sheets and extend for the whole length of the roof, and the bracing is bolted to these purlins.

By this method of construction, and the use of corrugated roof sheets of sufficient strength to serve the double purpose of acting as a curved rafter, and as a weather protection, spans over 55 feet have been erected. It will not, however, as a rule be found economical to exceed about 35 feet span with this type of roofing; and as the life of this structure depends on the strength of the covering, it is seldom justifiable to provide self-supporting roofs for permanent use, as this would entail great watchfulness and cost in protecting the sheeting against corrosion or decay.



The curved form of covering must be used for this type of roof, and for the larger spans the sheets may be arranged to *break joint* in the longitudinal joints; greater stiffness may be obtained in the complete sheeting by this arrangement of joints. The lower sheets of the roof, which have to resist a much greater strain than the upper ones, are sometimes made of a heavier gauge. Special attention is also necessary to ensure sufficient strength when bolting or riveting the several sheets together.

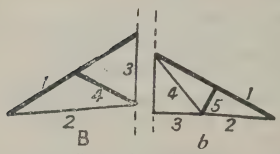
Ridged Roof Truss Multipliers.



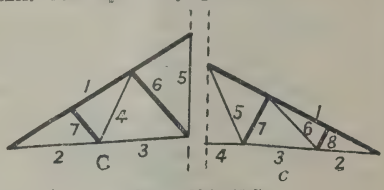
The determination of the stresses in the several members of any roof truss is usually a comparatively simple matter, although a considerable amount of time may sometimes be required to carry out this operation. Where any of the following types of trusses can be adopted, the above calculations can be much simplified and shortened.

For special water-tightness with slate or tile covering, one-third rise shown by capital letters) should be adopted; one-fourth rise is usual for corrugated sheet covering.

Rise of rafters, $\frac{1}{3}$rd and $\frac{1}{4}$th span. Rise of main ties, $\frac{1}{12}$th and $\frac{1}{16}$th span.



Spans to 15 ft.



Spans, 46 to 60 ft.

Compression shown by heavy lines. Tension shown by light lines.

Spans, 16 to 30 ft.

Spans, 31 to 45 ft.

In spans up to 60 feet the rafter is usually kept the same section throughout the full length; the table gives only the max. stress multiplier for rafters.

The max. practical span for any type of truss is indicated by multiplying the numbers of sections formed in the rafters by the joints in the same by $7\frac{1}{2}$ feet. Thus Type B gives $4 \times 7\frac{1}{2} = 30$ feet max. span, and Type D $= 8 \times 7\frac{1}{2} = 60$ feet max. span.

Purlins are assumed to be set at the joints; if not, allowance must be made for the extra stress due to the bending tendency produced.

It is also assumed that the trusses are fixed at both ends; if this is not so, the stress in some members may be increased by about 10 per cent.

The multipliers in the following table are calculated as for *unit load and unit span*. Thus for dead-load stress the actual dead load of truss covering, etc., is multiplied by the particular dead-load multiplier for the required member; for live-load stress, the live load from the actual normal wind pressure on one side of the truss is used along with the particular live-load multiplier. Both stresses added together give the max. stress on the member.

600	800	1020	1280	1530	2100	2250	Square Feet.

It is a bad practice to fasten zinc-iron sheets together with iron or steel rivets. These soon rust if not painted, and the rust penetrates through the edges of the iron encircling the rivets, and thus proves disastrous. Only zinc, or zinc-covered rivets, should be so used.

The great objection to iron as a roofing material is the drip from the moisture which condenses on the underneath side of it.

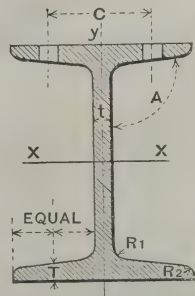
PAINTING FOR GALVANISED IRON ROOFS.

Paint adheres badly to new galvanised iron, but after a few years it will do so readily and will add greatly to its life. In order to make paint adhere to new galvanised iron, brush it over with the following mixture : Chloride of Copper, 1 part ; Nitrate of Copper, 1 part ; Salammoniac, 1 part ; Water, 64 parts, to which is added 1 part of Hydrochloric Acid. This mixture turns the galvanised iron black ; it should be left for at least 12 hours before being painted.

It is stated that paint will adhere to galvanised iron if the surface is washed with vinegar before painting.

(See also ' Painting,' Section XXXIX.)

VARNISH FOR GALVANISED IRON ROOFS.



Heat 100 gallons of tar to a low boiling point, and add 100 lbs. of fresh slaked lime, sifted over the top and then worked down. Boil this mixture until it becomes pasty. Let it settle for a few minutes and then add 20 lbs. of tallow and 5 lbs. of powdered resin. Stir until thoroughly mixed and all ingredients dissolved ; then allow to cool. The mixture should not be raised to a higher temperature than 100 degs. F. If too thick, it can be thinned down with paraffin or naphtha.

TRANSVERSE STRENGTH OF CORRUGATED IRON.

If W = breaking weight in tons (distributed) ; L = unsupported length of sheet in inches ; t = thickness of sheet in inches ; b = breadth of sheet in inches ; d = depth of corrugations in inches ;

$$W = \frac{44{\cdot}6\ t\ b\ d}{L}$$

The properties of British Standard Sections in above table are published by permission of the Engineering Standards Association. (*Dorman, Long & Co. Ltd.*)

REDPATH, BROWN
& CO. LTD.
CONSTRUCTIONAL ENGINEERS

Registered Office:
2 St. Andrew Square, EDINBURGH.

All types **Steel Structures**, complete **Steel Frame** or **Composite Buildings** for manufacturing or storage purposes. **Heavy and Light Girder Work, Stanchions, Gantries, Roof-work, Stagings,** Hay Sheds, etc., etc.

DESIGNS made and material systematically marked to ensure easy erection abroad.

Economical designs and estimates on application.

Branches:

EDINBURGH: St. Andrew Steel Works, Albion Road.
Telegrams: 'Redpath, Edinburgh.'

LONDON: 3 Laurence Pountney Hill, E.C. 4.
Telegrams: 'Arbee, Cannon, London.'

MANCHESTER: Westing House Road, Trafford Park.
Telegrams: 'Purlin, Manchester.'

GLASGOW: Office, 19 Waterloo Street.
Telegrams: 'Joists, Glasgow.'

Also at NEWCASTLE, BIRMINGHAM, MIDDLESBRO', BELFAST and DUBLIN.

See also following page.

REDPATH, BROWN

& CO. LTD.

IRON & STEEL MERCHANTS

STOCKHOLDERS

AND CONSTRUCTIONAL ENGINEERS.

Registered Office:
2 St. Andrew Square, EDINBURGH.

Sectional Material of all Standard shapes and sizes for Builders, Engineers, Shipyards and Collieries, cut to any required length and **despatched same day as ordered.**

Stocks of Steel **Joists, Channels, Angles, Tees, Rails, Bars,** etc., always on hand. Tonnage carried largest in the United Kingdom.

Joist sections for **PIT PROPS (STEEL)**; arched type complete with fishplates and bolts; straight beam type, holed if required.
Immediate delivery, any section, any quantity.

PROMPT DESPATCH AND RELIABILITY is a speciality in this department of our business.

BRANCHES: EDINBURGH, GLASGOW, LONDON, MANCHESTER, MIDDLESBRO', BIRMINGHAM, NEWCASTLE, BELFAST and DUBLIN.

BRITISH STANDARD SECTIONS.*

The British Engineering Standards Association revised their lists of Rolled Steel Sections for structural purposes on July 1920, and issued the same in August 1920. These comprise seven different sections, viz. (1) Equal Angles, (2) Unequal Angles, (3) Bulb Angles, (4) Bulb Plates, (5) Channels, (6) Beams, and (7) T Bars.

The following are abbreviated tables showing some of the standard dimensions recommended. Attention is directed to the footnotes on pp. 318, 319.

* Abstracted by permission of the British Engineering Standards Association.

8	3½	20·21	0·32	0·52	0·54	0·27
9	3½	22·27	0·34	0·54	0·54	0·27
10	3½	24·46	0·36	0·56	0·54	0·27
12	3½	25·25	0·35	0·50	0·54	0·27
12	4	31·33	0·40	0·60	0·60	0·30
15	4	36·37	0·41	0·62	0·60	0·30
17	4	44·34	0·48	0·68	0·60	0·30

In the complete table eighteen sizes are given. All sizes are in inches.

The alterations from the original to the revised sections given in this and the preceding page will take place, particularly in the larger sizes, only as the rolls wear out, or break, and thus require replacing. For some time, therefore, it will be necessary to enquire as to sections available.

The above tables are complete. All sizes are in inches.

For a considerable time the majority of the above sections will not be available, owing to the cost of providing the sets of rolls required for each size, and it will be necessary to utilise the present sections. For particulars of these present available sections of beams, a reference should be made to the table on p. 312, where all present British Standard Beams are marked BSB 1 to 30.

JOINTING BEAMS—TENONS—STRUTTING AND PUGGING—STRENGTH AND STIFFNESS OF BEAMS AND POLES—ROOFS AND ROOFING—FLOORS—JOISTS—FIRE-RESISTING FLOORS—EXPANDED METAL—PARTITIONS—STAIRS

(With Contributions by Alexander Drew, M.I.Mech.E., M.C.I., and Reginald Ryves, A.M.Inst.C.E.)

and

RUBEROID ROOFING

Completes the design

ALWAYS specify Ruberoid as the roofing. Lower in prime cost than slates, iron, tiles, zinc, or asphalt, yet it is durable and more reliable. Over and above the wonderful service there is the extra advantage of lightness in weight, which means considerable savings in timber costs. **Ruberoid is an economy from every point of view.** Its record runs back for over 30 years, and it is to-day in use in every town of importance throughout the world on all types of roofs and buildings. Avoid imitations.

SECTION VII

JOINTING BEAMS—TENONS—STRUTTING AND PUGGING—STRENGTH AND STIFFNESS OF BEAMS AND POLES—ROOFS AND ROOFING — FLOORS — JOISTS — FIRE-RESISTING FLOORS — EXPANDED METAL — PARTITIONS —STAIRS.

JOINTING BEAMS.

Fishing.

To resist Tension.—For lengthening ties a plain fished joint is most economical for labour and material. The two ends of the beams are butted together, and secured on each side by means of bolts, as shown by fig. 414, which shows the fishing of a 6-in. × 4-in. beam with an iron plate on one side and a wooden plate on the other, the bolts being 1 in. in diameter with 1½-in. heads, and the washers 2½ ins. × ¼ in.

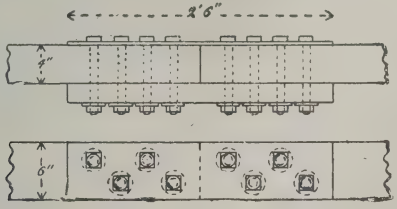

FIG. 414.

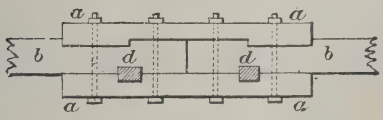

FIG. 415.

Another method is shown by fig. 415.

In this method, in order to relieve the strain on the bolts, the beam is indented or tabled as shown on upper side, or joggles or keys, *d*, *d*, are inserted. In either case the effective area is reduced by the indents or keys. The joint sectional area of the fish-pieces, *a*, *a*, should equal that of the beam, *b*. The joint sectional area of bolts should be at least one-fifth that of timber minus bolt-holes. Bolts are better square than round. Large washers should be under bolt-heads and nuts; for oak the washers should be 2½ times diameter of bolt, and for fir 3½ times.

Scarfing.

To resist Compression (fig. 416).—The bearing surfaces, *e*, *e*, should always be perpendicular to compressing force. Fig. 417 is a more elaborate form.

FIG. 416.

FIG. 417.

The lengths of scarfs should bear the following proportions to the depth :—

Wood.	Without Bolts.	With Bolts.	Bolts and Indents Combined.
Hard wood (oak, ash, elm) . .	6	3	2
Fir and straight-grained woods .	12	6	4

The sum of the depths of the indents should equal $1\frac{1}{2}$ depth of beam.

If assisted by fish-plates, it may be equal to the strength of a simple fished joint, which is as strong as the tie itself, less one rivet hole ; and no advantage is gained by making the joint complicated, but it should be formed similar to that shown by fig. 416.

To resist Tension.—Fig. 418 is often used. It will hold without bolts or straps. At *c* a key or joggle of hard wood is inserted, wedged in so as to tighten the joint moderately ; depth of key

FIG. 418.

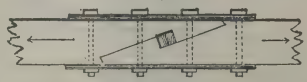

FIG. 419.

one-third depth of beam. This joint has only one-third the strength of solid timber tie ; it may be increased by bolting an iron fish-plate on each side, as in fig. 419.

FIG. 420.

To resist Compression and Tension.—Fig. 420 is suitable. The wedges at *c* are only required when bolts are to be added, in which case they are used to bring the parts together before the bolts are inserted, in order to prevent violent strains on the latter.

To resist Cross Strains.—Fig. 421 is the best. The joint at *a*, being in compression, should be kept square ; the lower, having to resist tension, may be oblique. There should be as great a thickness as possible at *b c*. To resist cross-strain, the scarf is strongest when made vertical, *i.e.*, the pressure in the figure being at right angles to the paper.

FIG. 421.

FIG. 422.

To resist Cross Strain and Tension.—The resistance to tension is given by indenting the beam and inserting wedges, as shown in fig. 422.

T Joint.

A very effective method of securing two pieces of wood, A and B, at right angles to each other, is to insert in a mortice hole in B a piece of aluminium *a* which has been drilled with a hole into which an ordinary wood screw *s* is forcibly screwed. The aluminium being comparatively soft enables the wood screw to readily work its way through the hole, whilst it forms a nut which enables the screw to be very tightly screwed up.

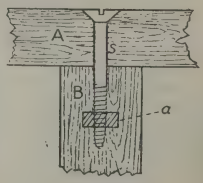

FIG. 422A

Building-up.

For building-up or joggling beams the method shown by fig. 423 may be adopted. This figure shows a portion of a 9 × 18-inch beam, 22 feet long, formed of two 9 × 9-inch beams secured

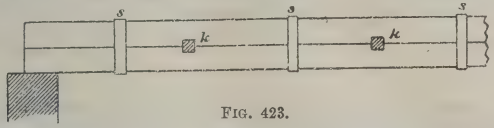

FIG. 423.

by wrought-iron straps, *s*, *s*, *s*, each 2 × $\frac{5}{16}$ inches; keys, *k*, each 2 × 2 inches, prevent the two pieces of which the beam is formed from sliding on one another.

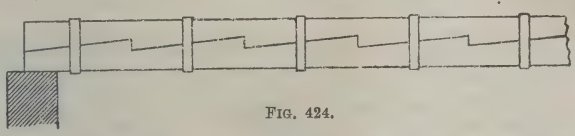

FIG. 424.

Fig. 424 shows a similar beam with the two halves indented the one into the other so as to prevent sliding.

Mortise and Tenon.

FIG. 425.

Mortising Upright into Horizontal.—The tenon, T (fig. 425), is usually one-third breadth of vertical. The pin-hole, if any, is generally placed at one-third length of tenon from shoulder, *s s*, and its diameter=one-fourth thickness of tenon. The mortise is made a little deeper, so that the shoulder may bear well; *r* is the *root*; C, C are the *abutment cheeks*.

Mortising Horizontal Beams.—The tenon is a projection from the end of the cross-beam, fitting closely into a mortise cut in the side of the main beam. It should be at the middle of its depth, so that the centre of the mortise may be at the neutral axis. Practically its lower edge is generally *on* the neutral axis.

Shouldered or Tusk Tenon.

To keep a cross-beam steady in its position a tenon requires length; to bear its share of load it requires depth; but a tenon long and deep would weaken the main beam too much. To avoid this a shouldered tenon is used. G (fig. 426) is the girder of a floor, B the binding joist, *a* the shoulder, *b* the tenon. The shoulder penetrates the girder about one-sixth depth of joist. Depth of tenon about one-sixth depth of joist; length about twice its depth, or it may be carried right through a thin girder and pinned, as in the case of a trimmer running into a trimming joist. Care should be taken that both tenon and shoulder bear exactly. Tredgold says the tenon should be one-third depth of joist above its lower edge. It should be, however, in the neutral axis.

FIG. 426.

Post and Beam Joints.—To frame a horizontal beam into the side of post the 'shouldered tenon' is used, but the long tenon should be on edge or have its narrowest dimensions horizontal.

When the beam rests on the top of the post, a small tenon in centre of post may fit into mortise on the under side of the beam. Or the post may fit into a shallow rectangular notch in beam, the notch being divided into two parts by a *bridle* left uncut in the middle of the notch, about one-fifth breadth of beam.

Wedges.

When the end of the tenon is seen, it is kept tight by driving wedges of hard wood dipped in glue or white-lead between tenon and sides of mortise. When end of tenon is not seen, small wedges, called *fox wedges* (fig. 427), are inserted in saw cuts in end of tenon; when tenon is driven home, they enter and expand it. The mortise is dovetailed or made slightly wider at bottom. This joint, when properly made, has the advantage that the post or style shrinks towards the shoulder and not away from it, and for this reason is sometimes employed for first-class work.

FIG. 427.

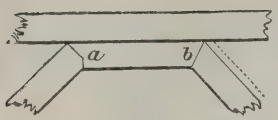

FIG. 428.

Joint of Straining-Beam.

In oblique joints under compression the joint should be either perpendicular to one piece, as at *a* (fig. 428), or bisect the angle, as at *b*; the latter is the best in the case given in the figure. With a thicker strut at *b* it would be as shown by the dotted line.

Joints in carpentry should have white-lead applied with a brush over the surface forming the joint.

Strutting.

Joists laid with boards on top, and lath and plaster underneath, are not found to be sufficient to prevent bending and vibration under pressure. To remedy this, which is injurious to walls and to timber, strutting is placed in straight, continuous rows, at intervals not more than 4 feet apart, which reduces to a great extent the defect.

The following are three methods of strutting :—

Herring-bone Strutting.—This consists of pieces about 2 inches square fixed as shown in fig. 429.

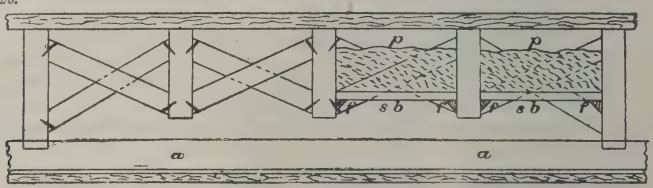

FIG. 429.

It is usual, instead of boring holes for nails, to make a saw cut at ends, and through this channel to drive the nail. By doing this any danger of splitting is avoided. This method has the recommendation that it acts where its leverage to prevent bending is greatest, viz., at the edges of joists, and is used largely in dwelling-houses.

FIG. 430.

Solid Strutting.—1 or 1½-inch boards, nearly the same depth as joists, are cut in tightly, and nailed between joists, as in fig. 430. This method is largely used for floors of factories and heavy buildings; and if cut so that the entire shoulder butts against the joists, is undoubtedly the firmest method; but unless care is exercised, the shoulders are apt to bite on the centre only. Sometimes long bolts, either of round bar or gaspipe, are passed through all the joists, and the strutting squeezed together with the joists and held tightly.

Key Strutting.—In this method struts are tenoned at their ends, and pass through mortises cut in the joists, and are secured with wooden keys. The method is expensive, weakens the joist, and altogether is a defective and unsatisfactory arrangement.

Pugging.

To prevent sound, sound-boarding, *s b* (fig. 429), is supported by fillets, *f*, *f*, cut diagonally out of 2-inch × 1½-inch stuff nailed to bridging joists half-way between floor-boards and ceiling joist, *a*, *a*; over these pugging, *p*, *p*, of coarse plaster about 1½ inch thick is put. Dry moss or a mixture of lime mortar, earth, and smith's ashes, or chopped straw, is sometimes used instead of plaster. Strips of felt are sometimes placed between the joists and boarding to deaden sound.

Strength and Stiffness of Beams and Poles.

b = breadth, d = depth, L = span.

Strength of Rectangular Beams.—For fir, safe distributed dead load, in cwts.

$$= \frac{bd^2 \text{ in inches}}{\text{L in feet}}.$$

For cedar and mahogany, about the same load as for fir.

For larch	¾	Above load for fir.
For beech, Dantzic oak	1½	
For English oak, ash	1½	
For teak	1¾	
For greenheart	2	

This formula gives a theoretical factor of safety of about 8; the practical factor of safety for large scantlings is about 5.

Strength of Circular Poles is $\frac{6}{10}$ strength of square beam, diameter of pole being equal to side of square.

Stiffness of Beams and Poles.—When the beam or pole is loaded with the safe load given above the deflection will be about $\frac{1}{50} \cdot \frac{\text{L}^2 \text{ in feet}}{d \text{ in inches}}$ for fir, oak, mahogany; for teak, about half that for fir.

Deflection of Beams.

In timber beams for permanent purposes, supported or fixed at both ends, the deflection usually allowed is $\frac{1}{450}$ inch per foot run; $\frac{1}{450}$ for those fixed at one end.

$$\text{V} = \frac{n\text{W}c^3}{e\text{I}},$$

where

V = deflection in inches, W = load in pounds, c = length in inches for beams fixed at one end, half length if supported or fixed at both ends; I = moment of inertia, e = modulus of elasticity (page 263)

Description.	Value of n.		
	Uniform Cross Section.	Uniform Strength and Depth.	Uniform Strength and Breadth.
Fixed at one end, loaded at other	$\frac{1}{3}$	$\frac{1}{2}$	$\frac{2}{3}$
" " loaded uniformly	$\frac{1}{8}$	$\frac{1}{4}$	$\frac{1}{2}$
Supported at both ends, loaded in middle	$\frac{1}{6}$	$\frac{1}{4}$	$\frac{1}{3}$
" " loaded uniformly	$\frac{5}{48}$	$\frac{1}{8}$	·1427
Fixed at both ends, loaded in middle	$\frac{1}{24}$		
" " loaded uniformly	$\frac{1}{48}$		

In the case of a beam of uniform strength, fixed at both ends and loaded at a point distant a_1 from one end and a_2 from the other, the deflection at point of application of load is—

$$\text{V} = \frac{(a_1 a_2)^2 \text{W}}{6e\text{I}c}.$$

The greatest deflection is at a point distant from one end $= a_2 - \sqrt{\frac{1}{3}a_2(a_2 - 2a_1)}$, a_2 being the larger division.

TABLE OF MOMENTS OF INERTIA.

Section of Beam.	I =	Section of Beam.	I =
Rectangular and square	$\frac{bd^3}{12}$	Ellipse, vertical semiaxis a, horizontal c	$\frac{\pi}{4}ca^3$
" hollow, $bd - b_1d_1$, also I-shaped section, where d_1 = depth of hollow parts, b_1 = sum of breadths of hollow parts	$\frac{bd^3 - b_1d_1^3}{12}$	Ellipse, hollow	$\frac{\pi}{4}(ca^3 - c_1a_1^3)$
		Semicircle standing with semicircular part up or down	·11r^6
Circle, radius r	$\frac{\pi}{4}r^4$	Isosceles triangle, base = b, height = d, standing on either base or apex	$\frac{bd^3}{36}$
" hollow	$\frac{\pi}{4} \cdot (r^4 - r_1^4)$		

All dimensions in inches; $\pi = 3{\cdot}1416$.

ROOFS.

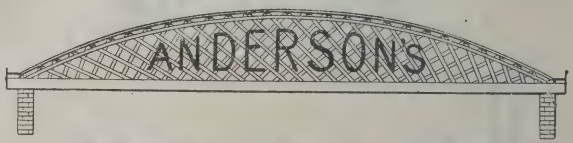
The British Roofing

'ROK' Roofing is made in Britain by British workmen, and is characteristic of British thoroughness.

For works and factories it has no equal. It is impervious to chemical action, whereas iron deteriorates rapidly under fumes. It will outlast iron and is cheaper than slates or tiles.

It is absolutely weather-proof in all climates and under all conditions, it ensures an even temperature, being a perfect non-conductor, and it is permanent, needing no annual tarring or other coating.



When you buy the BRITISH you buy the BEST—'ROK' is the BRITISH Roofing.

Write a postcard for the illustrated 'ROK' Booklet and keep it by you for reference.

ROACH ROAD WORKS, OLD FORD, LONDON, E.3.
and at Manchester.

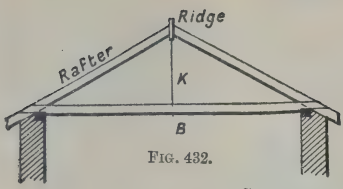

FIG. 432.

Single-span or Couple Roof.

May be used when walls can take the thrust without spreading; when they cannot, insert 4″ × 1″ binders as B (fig. 432), or $\frac{5}{8}$′ iron ties, at about 10′ intervals, supported by a light iron king rod (K).

SCANTLINGS FOR COUPLE ROOFS.

Pitch up to 30°, with countess slates on 1″ boards.

12	4 × 2	7 × 1½	6 × 2	18	5½ × 2	8 × 1½	9 × 2

Collar-beam Roof.

Ceiling carried on under side of rafter and collar; collar best placed half-way up rafter; used for roofs up to 18′ span, under the same conditions as to wind, walls, and ties as given for couple roofs (fig. 433).

The rafters are nailed to ridge-piece and bird's-mouthed over wall-plate, 1′ apart in the clear, or from centre to centre on very exposed sites.

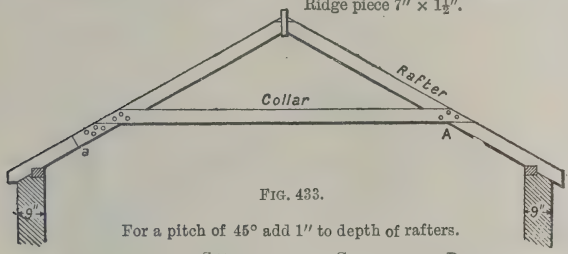

FIG. 433.

For a pitch of 45° add 1″ to depth of rafters.

SCANTLINGS FOR COLLAR-BEAM ROOFS.

Pitch up to 30°. If 45°, add 1″ to depth of rafters.

Span in Feet.	Rafters. For Countess Slates on ¾″ Boards, 1′ clear apart, or centre to centre if very exposed Site.				Collars.

10	1⅝ × 2½	1⅝ × 3	2¼ × 4	2¼ × 4½	2 × 2½	
12	1⅝ × 2¾	1⅝ × 3½	2¼ × 4½	2¼ × 5	2 × 2⅝	
14	1⅝ × 3	1⅝ × 3½	2½ × 5	2½ × 5½	2 × 3	
16	2 × 3½	2 × 3⅝	2½ × 5½	2½ × 6	2 × 3½	
18	2 × 3¾	2 × 4¼	2½ × 6	2½ × 6½	2 × 4	

* When used they act as ties, B (fig. 432), but without K. † Halve these collars on to rafters without cutting into latter. ‡ These rafters allow of the tension joint (fig. 434, page 330). If the collar is required halfway up, about one-fourth must be added to both breadth and depth of rafters, and ¾ in. to depth of collars. But with unstable walls, ties are far cheaper, and may be at long intervals if secured to wall-plates of sufficient width to take the thrust between the ties.

Fastenings of Collar-beam Roof.—Collars should never cut into rafters unless acting as ties; even then, the rafter being weakened at its weakest point, it has to be strengthened. If the walls, or plates can take the thrust, the collars are struts, and under transverse stress if ceiled. Collar roofs to wooden huts constantly push out the walls, owing to the wall-plate or top sill not being stiff enough. Fig. 434 shows method of fastening collar C to rafter R, when collar acts as a tie,

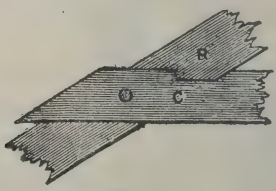

FIG. 434.

and, whether ceiled or not, it is better than a dove-tail; the collar and, rafter are both notched about $\frac{1}{3}''$. When collar is a strut it may be halved on, as at A (fig. 433, p. 329); when intended also to be ceiled it should, in addition, rest on a bearer spiked to side of rafter, as at *a* (fig. 433, p. 329), the rafter being uncut in either case. The rafters abut on the ridge, and are nailed to it. They are bird's-mouthed on to wall-plate.

King-Post Roof.

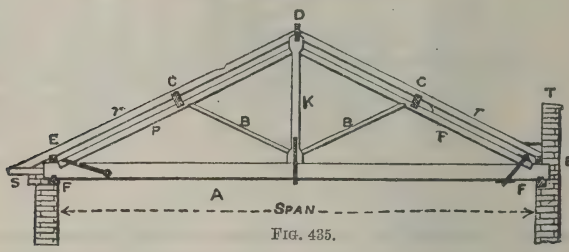

FIG. 435.

Used for spans from 20′ to 30′ (fig. 435).

A, tie-beam; B, braces or struts; C, purlins; D, ridge-board; E, pole-plate; F, wall-plate K, king post; P, principal rafter; *r*, small or common rafter; S, eaves boarding; T, parapet.

46	12½ × 6	6 × 5½	7 × 6	9 × 6	4¾ × 3	9 × 5½	5 × 2	8 × 2	4 × 4

Trusses, 10 apart; pitch of roof, 26° 33′, or ½; countess slates; timber, Baltic pine.
Wall-plates, F, 5″ × 4″ to 6″ × 4″; more if trusses are over openings.

Common Rafters.

12″ from centre to centre, or apart if not very exposed site.

Bearing in Feet.	Breadth in Inches.				
	1¾	2	2¼	2½	3
	Depth in Inches.	Depth in Inches.	Depth in Inches.	Depth in Inches.	Depth in Inches.
5	3	2⅞	2¾		
6	3¼	3⅛	3¼	3½	
8	4⅜	4⅝	4⅜	4½	4
10	6	5¾	5½	5⅝	5
12	7	6¾	6½	6⅝	6
14	8¼	8	7¾	7½	7
16	9½	9¼	8¾	8½	8
18	10½	10½	10	9½	9
20	11¾	11½	11	10½	10

Thin and deep rafters most economical; should not be thinner than 1¾″ to 2″, or may split when boards are nailed to them. For stone or tile covering should be one-third stronger.

Joints of Wooden Roofs.

Joint at Foot of Principal Rafter (fig. 437).—Wood, Northern pine, *i.e.* red fir; rafter, $4'' \times 5''$; tie, $10'' \times 4''$; *ad*, $3''$; tenon, $\frac{1}{3}$ width of rafter.

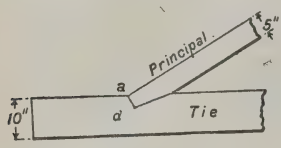

FIG. 437.

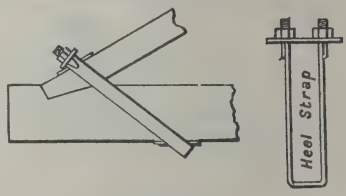

FIG. 438.

Iron Straps to Wood Roofs (fig. 438).—When longest unsupported part of tie beam

= 10 feet, strap should be . . . . . $1\frac{1}{2}'' \times \frac{3}{8}''$;
= 15 feet, " " . . . . . $1\frac{1}{2}'' \times \frac{1}{2}''$;
= 20 feet, " " . . . . . $2'' \times \frac{1}{2}''$.

The straps at the feet of the principal rafters may be of the same section as that for supporting the tie beam; a width less than $1\frac{1}{2}''$ is liable to cut into the fibres of the wood.

The strap in small roofs is generally fixed as shown on left-hand side of fig. 438.

Purlin.—Should be in pieces as long, and as nearly over strut B, as possible (fig. 439). The purlin, C, is notched over principal rafter, P, which is cogged to receive it; notches about $1'' \times 1''$. Common rafter, *r*, is notched on to purlin. The strut or brace, B, is tenoned into the principal rafter, P, as shown.

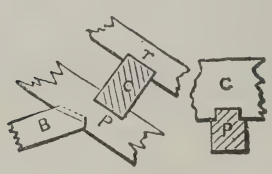

FIG. 439.

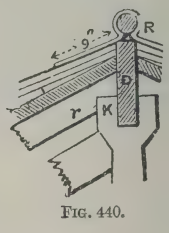

FIG. 440.

FIG. 441.

Ridge Board and Roll.—The ridge board, D (fig. 440), is let into king post, K, as shown. The common rafter, *r*, butts against and is nailed on to ridge board. R shows the ridge roll of wood with lead covering, ridge tiles, or Williams' patent ridge (fig. 441), in two pieces; the ends of the roll butt against each other, and are fixed with white lead, copper dowels, and 2" copper screws.

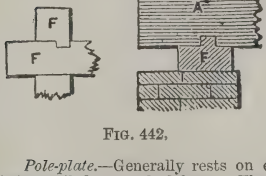

FIG. 442.

FIG. 443.

Wall-plate and Tie Beam.—Fig. 442 shows a wall-plate, F, cogged to receive tie beam, A, which should have a clear space round to prevent rotting. A stone template is sometimes substituted for the wall plate.

F, F, shows joint of wall-plates at angles of buildings, an arrangement which is better than a dovetail.

Rafter bird's-mouthed on to wall-plate or pole-plate, &c., spiked or skew-nailed down to it, is shown by fig. 443.

Pole-plate.—Generally rests on end of tie beam (fig. 435, page 330), or on foot of principal, being nailed or notched down. The position, however, depends upon the nature of the eaves.

King Post.—The king post, K (figs. 435 and 444), suspends the tie beam, with attached ceiling, if any, and also the principals, by means of the braces, B.

The principal rafter should abut square on the king post, as P. When head of post is not sufficiently long for this the joint may be made as P¹. The braces, B, should also abut perpendicularly on the king post. The ends of the principal rafters and braces are mortised into the king post.

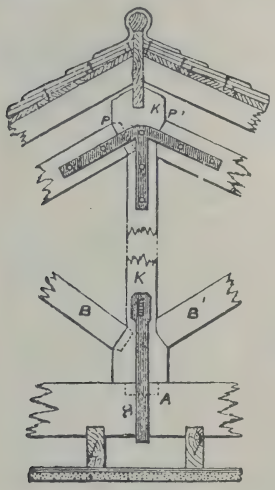

FIG. 444.

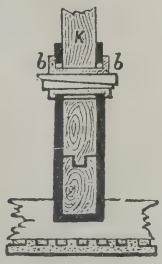

FIG. 445.

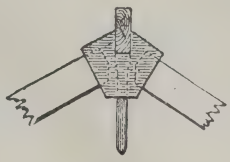

FIG. 446.

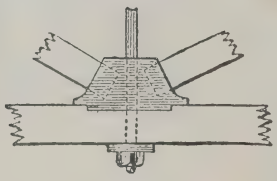

FIG. 447.

The king post is tenoned into the tie beam, A, with a short tenon, and fastened to it by an iron strap or *stirrup* iron. Gibs and cotters, as at *b*, *b* (fig. 445), enable the strap to be raised so as to tighten up the roof.

If a wrought-iron rod is substituted for a king post, its diameter in inches = square root of span of roof in feet × ·02.

Fig. 446 shows cast-iron head to receive rafters, and fig. 447 iron shoe to receive struts; a block of wood is often used for the feet of struts to butt against. When there are no gibs and cotters wedges may be driven in between underside of tie beam and foot of strap to force tie beam against foot of king post.

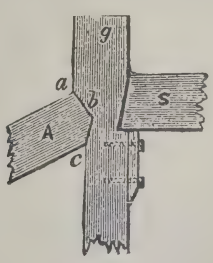

FIG. 448.

Queen Posts.—The abutments of the principal rafter, A, and struts of queen-post roof are the same as for the king-post. Joint of straining beam, S, with queen post, shown in fig. 448. If the head, *g*, of the post is narrow, the end of A should be cut away at an angle, *a b c*, so as to enable it to abut closely against the head; but if the latter is wide enough to admit of it, then the end of A may be cut square. If a wrought-iron rod is substituted for a queen post, diameter in inches = square root of length in feet of that portion of beam supported by queen bolt × ·29.

Pressure of Wind and Weight of Snow on Roofs.

The *Wind Pressure* is usually assumed to be equal to 40 lbs. per foot in cases where the inclination of the roof is 60°; for less angles than this the pressure is taken as follows :—

Inclination	5°	10°	15°	20°	25°	30°	35°	40°	45°	50°	55°	60°
Pressure in lbs. per sq. ft.	5·1	9·6	14·2	18·4	22·6	26·5	30·1	33·3	36·0	38·0	39·4	40·0

The *Weight of Snow* in Great Britain varies from 5 to 11 lbs. per cubic foot. It is not likely to accumulate on roofs to a greater depth than 6 inches; 5 lbs. per superficial foot of horizontal surface covered seems a quite sufficient allowance to make.

In Canada and the United States snow has been found in some instances to weigh as much as 30 lbs. per cubic foot some hours after it has fallen, and an allowance of at least 12 lbs. per superficial foot of horizontal surface covered should be allowed for it.

ROOFING MATERIALS.

Heat-Insulating Value of Roofing Materials.*

A National Physical Laboratory test of roofing by measuring the heat lost from a heated room leads to the remarkable conclusion that the rate of emission of heat by radiation from the covering surface has more effect on the inside temperature than the rate of conduction of heat through the material. This result is of importance in the roofing of large factories of a semi-permanent nature, where the temperature depends more upon the covering than in the case of buildings having a closed air space under the roof.

Old galvanised iron allows more heat to pass than glass, a remarkable result. Slates are good, but in proportion heavy. Deal boarding covered with asphalted felt, though thick, is not so heavy as Welsh slate, and is one of the best insulators. In this case its poor conductivity is evidently not negligible, and in all thick roofing materials it is probably of importance.

HEAT TRANSMITTED THROUGH ROOFING MATERIAL EXPOSED TO STRONG RADIATION.

Material.	Rise of Temperature in Testing Chamber Deg. C. per Minute.	British Thermal Units per 100 sq. ft. per Hour.	Thickness in Inches.	Weight in Pounds per Square Foot.
1. Bright galvanised iron sheet .	0·268	111	0·04	1·6
2. Galvanised iron, blackened below	0·40	108	0·04	1·6
3. Galvanised iron, blackened above	0·93	385	0·04	1·6
4. Galvanised iron, blackened above and below	1·40	581	0·04	1·6
5. Galvanised corrugated iron after one month's exposure to the weather	0·75	310	0·033	1·28
6. Do. one year	1·02	422	0·033	1·28
7. (6) painted black above . .	1·13	472	0·033	1·28
8. Roofing glass, serrated . . .	1·10	453	0·22	2·25
9. Welsh slate	0·81	337	0·17	2·9
10. Westmoreland slate . . .	0·60	248	0·25	4·8
11. ¾-in. T.G. deal covered with asphalted felt	0·30	124	1·0	2·6
12. Corrugated fibrocement after one month in use	0·78	325	0·2	1·8
13. Do. after one year in use . .	0·80	334	0·2	1·8
14. Do. painted dead black . .	0·82	341	0·2	1·8
15. Do. 'aluminium-finished' outside	0·50	207	0·2	1·8
16. Do. laid on top of thin asphalted felt	0·51	211	0·25	2·0

A suggestion was made in the National Physical Laboratory Report that air spaces in roofing materials might be advantageous. A satisfactory means of doing this is to lay corrugated asbestos cement plates on the thinnest asphalted felt or other light sheet material supported by the roof frames. The effect of this is shown by the table to be equal to that of an aluminium surface, and where heat insulation and lightness are of the first importance a strong and efficient roofing can be made in this way at a reasonable cost.

* W. M. Thornton, D.Sc., D.Eng., Armstrong College, Newcastle-on-Tyne; *Engineering*, October 19, 1917.

Bell's Poilite for roofs

Bell's Poilite asbestos-cement Standard tiles give a roof that is fully as durable and strong as the best natural slate roof. They are non-absorbent, fire-resisting and rot-proof, and, because of their light weight, effect great economies in transport, fixing and raftering. A Poilite roof hardens with exposure and is not affected by moisture or frost.

Size—$15\frac{3}{4} \times 15\frac{3}{4}$" for diagonal laying to laps of $2\frac{3}{4}$ up to 4". Approximate number per square, 100 for $3\frac{1}{2}$" lap.

Bell's Poilite corrugated sheets are best adapted for covering with economy of labour the roofs and external walls of large engineering and factory buildings, railway running sheds, breweries and the like, and they can be readily fixed to steel angles or to timber purlins. Their over-all width of 3' $7\frac{1}{4}$" affords a great advantage over corrugated iron sheets, with a standard width of only 27". Further, no painting or treatment of any kind is required to preserve the material. They are light in weight, rot and vermin proof, fire-resisting and non-conductors of heat and electricity.

Bell's United Asbestos Co. Ltd.

Pioneers of the World's Asbestos Industry

Southwark St. London. S.E.1.

Bell's Poilite for walls

Bell's Poilite asbestos-cement flat building sheets are impermeable and fire-resisting, rot and vermin proof, and non-conductors of heat and cold. These qualities render them an ideal material for external and internal linings for walls, partitions and ceilings. They are specially adapted for the ceilings of factories and workshops, entirely obviating the cracks and breakages occurring in plaster ceilings exposed to the vibration of machinery, or to excessive heat or moisture.

Poilite

Bell's Poilite flat building sheets were the first British asbestos-cement building sheets. They are immeasurably superior to plaster or boarding, and are quickly and easily fixed. The appearance of the sheets can be made most attractive by distemper or enamel, and the joints can be covered by wood moulding.

Standard sizes: 8 ft. × 4 ft., 6 ft. × 4 ft., 4 ft. × 4 ft.
$\frac{3}{16}$ in. thick and upwards.

Bell's United Asbestos Co. Ltd.

Pioneers of the World's Asbestos Industry

Southwark St. London. S.E.1.

'Poilite' Roofing Tiles.

'Poilite' is a tough, indestructible and practically unbreakable roofing material manufactured by *Bell's United Asbestos Company, Ltd.*

The constituents are Portland cement with asbestos, the latter being employed in its fiberised form, known as mineral flax, serving the purpose of an aggregate, thereby increasing the initial strength of the cement tenfold.

'Poilite' is produced in specially designed rolling mills, in the form of layers or films of cement and asbestos uniformly distributed and interlaced so as to constitute a species of tough woven fabric. The layers adhere so firmly to each other that, after reaching the mature stage, a 'Poilite' asbestos cement sheet is found on fracture to be void of all stratification or lamination. It will be readily understood that the fibre not only gives the product a pre-eminent degree of incombustibility, resiliency and durability in varying conditions of climate, but also the outstanding advantages of affording immense resistance to transverse mechanical and tensile stresses, which increase in ratio with its age.

The resistance to breakage of 'Poilite' tiles is exceptional. The immense toughness and strength of the tiles eliminates damage or breakage in transit, handling, and fixing. Tensile strength is 5,973 lbs. per square inch; crushing is 7,000 lbs. per square inch.

The weight of 'Poilite' tiles is relatively small, although reaching the necessary degree of resistance they only require to have a thickness of $3\frac{1}{2}$ to 4 millimetres. When laid diagonally, the weight of 'Poilite' roofing is about 22 lbs. per square yard, as compared with 80 lbs. for natural slates and 140 lbs. for ordinary mastic tiles. Lighter framework can therefore be employed when 'Poilite' tiling is used. Rafters can be spaced up to 2 ft. 6 ins. centres.

The tiles are made in terra-cotta and grey colours, and can be cheaply and quickly fixed to closeboarding or wood battens. When fixed diagonally, 85 standard tiles $15\frac{3}{4}$ ins. by $15\frac{3}{4}$ ins. holed for $2\frac{3}{4}$ ins. of lap are required to cover 100 square feet of plain roof area, which is sufficient for roofs with a pitch of 35° and over. For roofs of less pitch the lap should be increased proportionally.

Corrugated Asbestos Cement Sheets ('Poilite' Brand).

These sheets are made to a standard width of 3 ft. $7\frac{5}{16}$ ins., and in various lengths up to 8 ft.; allowing for a horizontal lap of 6 ins. and a side lap of $\frac{1}{2}$ ins., the actual cover of a full size sheet is 7 ft. 6 ins. by 3 ft. $3\frac{5}{16}$ ins. Four sheets will thus practically cover 100 square feet of roof area. In the case of steel framed roofs the sheets are secured to the angle irons with hook-bolts and limpet washers, and on to timber roofs with 3-inch screws and washers.

The weight of material when laid is about 320 lbs. per square.

Purlins can be spaced up to 3 ft. 9 in. centres.

These sheets are especially suitable for covering the roofs of factory buildings, railway and engineering sheds.

'Poilite' Asbestos Cement Building Sheets.

These flat sheets are specially suitable for external and internal wall and ceiling linings.

They are made in standard sizes 4 ft. by 4 ft., 6 ft. by 4 ft., and 8 ft. by 4 ft., from $\frac{3}{16}$ in. thick upwards.

Ceiling sheets $\frac{3}{16}$ in. thick, minimum thickness for walls $\frac{3}{16}$ in. Fire-resisting, damp and vermin proof.

The fire-resisting properties of 'Poilite' are due to the use made of asbestos in its preparation and it is accepted by the L.C.C., County and Borough Surveyors and by Fire Assurance Companies.

'Fibrent' Asbestos-Cement.

'Fibrent,' the registered trade mark for asbestos-cement sheets and slates manufactured by *The British Fibrocement Works, Erith, Kent*, sometimes termed Fibrocement, is a form of concrete or reinforced cement, the mineral fibres fulfilling this function of reinforcement, and the highest grade British Portland cement and specially selected asbestos fibre only being used for the purpose.

'Fibrent' Asbestos-Cement Slates.

These slates, manufactured in diagonal or honeycomb pattern, 12 ins. by 12 ins., $15\frac{1}{2}$ ins. by $15\frac{1}{2}$ ins., and 24 ins. by 24 ins., cut and holed for $2\frac{1}{2}$ ins. or other laps required, are of such compactness that absorption is reduced to approximately a quarter of the weight of water which an ordinary sand-faced roofing tile of good quality and of the same volume would absorb.

By exposure to climatic extremes the slates become absolutely impervious. They are non-conductive of heat or cold, fire resisting to the highest degree, of extreme durability, and possessing considerable elasticity are immune from cracking or scaling under frost or extremes of temperature.

'Fibrent' slates are extremely light, weighing when fixed about 20 lbs. to the square yard, thus great economy may be effected in general roof construction, rafters being spaced at a minimum of 24 ins. to maximum 30 ins. They may be fixed direct to light battens or rough boarding by means of two nails and a copper disc rivet and, invariably, a perfectly satisfactory, inexpensive and effective roof covering is the result. 'Fibrent' has been used upon a number of modern factories where slating is the roof covering with very satisfactory results.

'Fibrent' Asbestos Cement—*continued.*

'FIBRENT' DUCHESS SLATES, size 24 ins. by 12 ins., recently introduced, combine all the advantages of the diagonal or honeycomb patterns, and being fixed with straight cover similar to ordinary natural slates, may be used with quite satisfactory results for private dwelling-houses, etc., the cost of upkeep being reduced to a minimum. They are guaranteed against signs of disintegration during a period of twenty years.

All patterns of 'Fibrent' slates are manufactured in colours grey, red, or blue-black.

'FIBRENT' CORRUGATED ASBESTOS-CEMENT ROOFING AND BUILDING SHEETS,

manufactured upon the principle mentioned above, are the most modern form of product, and combine the advantages of corrugated metallic roofing in point of economy, and in addition they are non-conductive, fire resisting, practically everlasting in their original form, and require no treatment such as painting, etc.

These corrugated sheets are manufactured in lengths 4 ft., 5 ft., 6 ft., 7 ft., 8 ft., 9 ft., or 10 ft., 2 ft. 6 ins. wide, comprising nine 3 in. corrugations, and in standard $\frac{1}{4}$ in. thickness. They are also manufactured to any radius for curved roofs.

'Fibrent' asbestos-cement corrugated sheets are used for roofs upon all classes of commercial and domestic buildings, and are fixed by means of ordinary galvanised drive screws and washers to wood purlins, or by galvanised hook bolts and washers to steel angles, in the same manner as metallic roofing of a similar form.

'FIBRENT' RIDGE TILES,

manufactured in shapes half round, plain angle, or shaped roll, up to 4 ft. lengths, form a very suitable capping for ridge and hips upon all kinds of roofs.

'FIBRENT' FLAT SHEETS

combine all the advantages claimed for the slates and corrugated sheets, and are used with great advantage for external or internal walls, partitions, ceilings, etc. They are fixed by means of ordinary nails, which penetrate quite easily.

The standard sizes of 'Fibrent' flat sheets are 8 ft. by 4 ft., 4 ft. by 4 ft., and 6 ft. by 3 ft.; thicknesses varying from $\frac{1}{8}$ in. to $\frac{1}{2}$ in., intermediate thicknesses being $\frac{5}{32}$ ins., $\frac{3}{16}$ ins., $\frac{1}{4}$ in., $\frac{5}{16}$ in., $\frac{3}{8}$ in. For external walls, where normal strength is required, $\frac{3}{16}$ in. or $\frac{1}{4}$ in. thickness prove perfectly satisfactory, and for internal linings, panels, or walls, $\frac{3}{16}$ in., or for ceilings, $\frac{5}{32}$ in. are most adaptable.

'Fibrent' asbestos-cement flat sheets can be cut to requisite sizes by means of a good hand-saw at the time of fixing, and, in consequence, possibility of waste is obviated.

For panel effect, cover strips, in required widths and thicknesses, are obtainable, and when fixed the sheeting in its entirety may be distempered, enamelled, grained, papered, etc., after an application of concentrated size, thus producing effects which are obtainable with other methods of forming partitions or ceilings.

Ruberoid Roofing.

Ruberoid, an exceptionally light material (made in England and used generally throughout the world for over 30 years), weighing only $\frac{1}{3}$ to $\frac{1}{2}$ lb. per sq. ft., is manufactured in rolls 36 ins. wide, 72 ft. long, containing sufficient material to cover 2 squares. On pitched roofs the Ruberoid is laid from ridge to eaves on wood sheathing boards, which should be close butted. The arris at ridges and hips should be slightly rounded. The strips of Ruberoid are joined by lapping at the seams at least 2 ins. (fig. 470), well coating with Ruberoid cement between the laps and nailing to the boards down centre of each seam, spacing the nails 2 ins. apart. The nail heads and seams are further protected by being painted with Ruberoid cement.

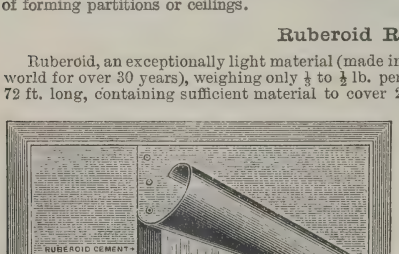

FIG. 470.

On flat roofs of wood the same method is employed. No drips or rolls are needed. Roofs should fall 2 ins. in 10 ft. to allow drainage. Ruberoid can be flashed to parapet walls in the same manner as lead, and box gutters, cesspools and outlets lined with it.

Flat concrete roofs are waterproofed with one or two layers of Ruberoid cemented to the surface of the concrete with Ruberoid compound; the joints in this case are lapped 3 inches. This method of waterproofing is also largely used for cracked concrete and asphalt roofs.

BRITISH FIBROCEMENT WORKS

BOOKS for STRUCTURAL ENGINEERS.

Crown 8vo, Limp Cloth, Rounded Corners, 3/- net.

The Reinforced Concrete Regulations of the London County Council.

Made July 1915, under the London County Council General Powers Act, 1909, approved by the Local Government Board, and now in force.

A Handy Guide, containing the Full Official Text, with Explanatory Notes, Diagrams, and Worked Examples.

By EWART S. ANDREWS, B.Sc.Eng., M.C.I.,
Consulting Structural Engineer.

Although these Regulations apply only to the London area, they are likely to be adopted throughout Great Britain, because they contain the most detailed requirements of any official Regulations in the world, and also they have received the approval of the Local Government Board. Provincial authorities who apply for loans upon reinforced concrete construction will probably therefore conform to the Regulations which the Board have already approved.

Crown Octavo. Containing 154 pages. Bound in cloth, 5/- net.

Estimating for Reinforced Concrete Work

A Handbook for Measuring and Pricing Reinforced Concrete. Compiled for the use of Engineers, Architects, and Estimators

By T. E. COLEMAN
(*Major, Staff for Royal Engineer Services*),

Author of 'APPROXIMATE ESTIMATES,' 'THE CIVIL ENGINEER'S COST BOOK,' 'RETAINING WALLS IN THEORY AND PRACTICE,' etc.

This volume is designed to assist Engineers and Architects in the preparation of estimates and bills of quantities for Reinforced Concrete Works. The various notes and data which are ordinarily required for this purpose have here been brought together in a convenient form so as to provide a practical handbook for ready reference.

Full details of the procedure to be adopted in taking off quantities for reinforced concrete buildings, bridges, retaining walls, piles, etc., are given, including the mode of measuring all the various items of materials and workmanship. In addition, a comprehensive series of typical items and descriptions for reinforced concrete are systematically grouped for guidance and reference in preparing Bills of Quantities.

B. T. BATSFORD, LTD., 94 High Holborn, London.

F. 337

A Ruberoid roof being airtight, proper ventilation should be provided at the highest point.

As it is easily laid in position and is unaffected by moist heat it is largely used in tropical countries, particularly on the West Coast of Africa, in India, and South Africa.

Paint does not adhere well to it, and it should not be tarred ; if desired it can be coated with Ruberine roof paint, which is made in three colours, red, green, and black. Ruberoid, being acid and alkali proof, can be safely used on chemical works and other places where it is subjected to fumes, as well as on the sea-coast.

Price of Standard Ruberoid Roofing per roll, to cover 200 sq. ft. of roof, including accessories :—

½-ply Grey	. 29*s.* 0*d.* per roll.	2-ply Red	. 56*s.* 0*d.* per roll.
1-ply „	. 36*s.* 0*d.* „ „	2-ply Grey	. 42*s.* 9*d.* „ „
1-ply Red	. 45*s.* 6*d.* „ „	3-ply „	. 51*s.* 9*d.* „ „

The manufacturers are *The Ruberoid Co. Ltd.*, 28 Waterloo House, Knightrider Street, London, E.C. Prices are quoted on application, fixed complete in any part of the United Kingdom.

Approximate Weight of Ruberoid Roofing.
(Rolls 36 inches wide by 72 feet long.)

'Rok' Roofing.

'Rok' roofing (manufactured by ***D.** Anderson & Son, Ltd.*, Lagan Works, Belfast, and Roach Road, Bow, London, E.) forms a permanent and easily applied roof covering, and can be used in place of slates, tiles or corrugated iron. Only the highest grade of wool felt is used in its manufacture. This is saturated with an elastic waterproofing compound, which does not dry out or evaporate in any climate, as it contains no oils, or volatile matter. The coating on the surface is a permanent one, composed of a natural bitumen of very high melting point. There is nothing of an organic nature in either the saturating or coating compound. It is acid and alkali proof and not affected by white ants. It is suitable for pitched, flat, or circular ('Belfast') roofs, and for reinforced concrete roofs it will be found to make a thoroughly water-tight job.

Rain water from roofs covered with it can be used for domestic purposes.

Being an excellent non-conductor, it ensures an even temperature, and is therefore an ideal roofing for hot climates.

It is laid on close jointed boarding, which should not be less than ¾ in. thick, either plain edged or tongued and grooved. The purlins or rafters should be so spaced that there is no appreciable spring in the boarding.

It may be fixed either longitudinally from gable to gable, or vertically from eaves to eaves. It is, however, considered advisable to lay it crosswise to the boarding. The joints should be formed with at least 2 ins. overlap, being stuck together with 'Rok' cement and carefully nailed with tacks not more than 2 ins. apart placed in the centre of the seams. The heads of the tacks where exposed and the outside of the seams should be dressed with 'Rok' cement.

'Rok' roofing is supplied in rolls of 72 ft. by 3 ft. wide, in the following grades :—

½-ply average weight	50 lbs. per roll	. .	Prices furnished on application to the manufacturers.
1-ply „	62 „	. .	
2-ply „	82 „	. .	
3-ply „	104 „	. .	

(The above weights do not include the nails and cements.)

Sufficient tacks and cement to fix the roofing are supplied free by the manufacturers with each roll. Each roll, if carefully laid, should cover 200 sq. ft.

The manufacturers will undertake to carry out the fixing if desired.

'Rok' roofing may also be used on concrete, fixed with special 'Rok' mastic, and it is advisable to write the manufacturers for full directions as to the method of applying.

It may also be used for covering flats and gutters. In this case it is recommended to use two layers, the first layer being tacked to the boarding, and the top layer stuck to the under one with 'Rok' mastic. In this way no nail heads are exposed. Flashings to walls, round lights, etc., may be made in the material.

'Rok' roofing as supplied is a uniform grey colour, but special paint, known as 'Rokolor,' is supplied by the manufacturers in red and green or black.

'Rokalba' (asbestos-coated 'Rok'), having asbestos fibre bedded in the coating on one side, is also manufactured by D. Anderson & Son, Ltd.

The weight of this material is as follows :—

No. 1	average weight	70 lbs.
No. 2	,,	98 ,,
No. 3	,,	120 ,,

(The above weights do not include the nails and cement.

Prices will be furnished on application to the manufacturers. The method of laying 'Rokalba is the same as 'Rok' roofing.

FLOORS.

Single-joisted Floor.

Fig. 471 shows a single set of bearers, *b*, called common or bridging joists, to which ceiling joists, *a*, are attached when desired. The ceiling is more liable to crack with a single than with a double floor, but this may be obviated by making every third or fourth joist deeper, and fastening the ceiling to them only. The ceiling joists are notched, and nailed to the joists *b*.

FIG. 471.

This is the strongest and cheapest floor, the maximum strength to be got from a wooden, untrussed floor being with deep single joists placed close together, and such a floor with a plaster ceiling below is fire-resisting.

Double Floor.

Figs. 472, 473, show a double set of bearers, *i.e.*, binding joists or binders, *d*, and bridging joists, *b*. The binders are the chief supports of the floor, and are generally about 6′ apart. The bridging joists are notched over them, and any ceiling joists, *a*, under them. The bridging as

FIG. 472.

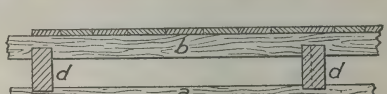

FIG. 473.

well as the ceiling joists can be framed between the binders, or supported by fillets spiked to their sides when it is required to reduce the depth of the floor. The binders rest on stone templates.

Framed Floors

differ from double floors only in having the binders framed into a third set of bearers, called girders.

The girders, *a* (fig. 474), are the chief support ; the binding joists, *d*, are tusk-tenoned into them (fig. 426, page 325) ; the latter support the bridging joists, *b*, and ceiling joists, *c*. The

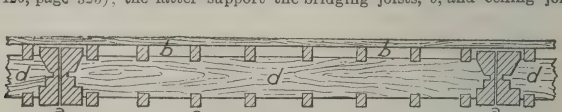

FIG. 474.

girders should not be more than 8′ to 10′ apart. When the breadth of a girder is considerable it is sometimes sawn down the middle, reversed, and bolted together with sawn sides outwards. slips being placed between to allow air to circulate freely. This allows centre of balk to be examined, and is less liable to rot ; it slightly diminishes strength of girder. Such girders are sometimes strengthened by wrought-iron flitches bolted in between the two halves.

The ends of girders should be on stone templates (fig. 475), and should have a space round them to prevent decay.

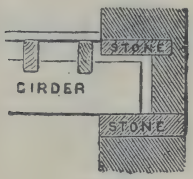

FIG. 475.

Camber of Joists.

Floors, when first framed, should always be kept about $\frac{3}{4}''$ higher in the middle than at the sides of a room; also the ceiling joists should be fixed about $\frac{3}{4}''$ in 20′ higher in the middle than at the sides of room. If laid level they are sure to sag when used.

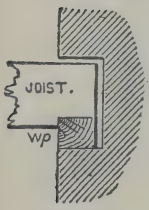

FIG. 476.

Wall-plates for Floors.

On ground-floor generally placed on offset. May be let into wall, care being taken that free space is left round end of joists or girders, as in fig. 476; but, as the wall-plate is perishable, the effective strength of the wall is reduced by the width of the plates. They should, if possible, rest on stone corbels or brick corbel courses. The joists are usually only nailed to the wall-plates, but sometimes notched (fig. 476) or cogged; the latter is quite unnecessary.

For 20′ bearing, wall-plate is $4\frac{1}{2}'' \times 3''$; for 30′ bearing, $6'' \times 4''$; for 40′, $7\frac{1}{2}'' \times 5''$.

(*Tredgold.*)

Wooden Girders for Floors,

10 feet from centre to centre.

b = breadth; d = depth, in inches; L = length, in feet.

$$d = \sqrt[3]{\frac{L^2}{b}} \times 4{\cdot}2 \text{ for fir; by } 4{\cdot}34 \text{ for oak.} \qquad b = \frac{L^2}{d^3} \times 74 \text{ for fir; by } 82 \text{ for oak.}$$

To obtain maximum stiffness make $b = \frac{5}{7}d$.

Girders of Wood with Wrought-iron Flitches.—The wood and iron of these girders bend differently; therefore, only half strength of wood is exerted if the iron is not unduly strained. If thickness of iron is less than $\frac{2}{17}$ that of wood, the beam will be weaker than without iron. If thickness of iron = $\frac{2}{17}$ wood, the beam will have the same strength as if without iron, and be twice as stiff. If thickness of iron exceeds $\frac{2}{17}$ wood, beam will be stronger than plain wooden beam.

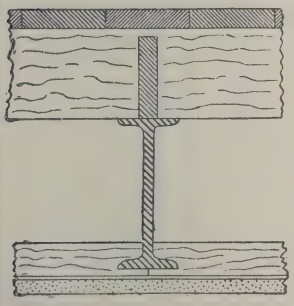

FIG. 477.

Wrought-iron Binders.

Rolled-iron joists are now extensively used as binders, the upper flange of which may support the floor joists, and the lower flange the ceiling joists, as in fig. 477.

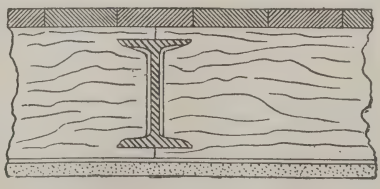

FIG. 478.

When the depth of the floor is required to be as shallow as possible, rolled-iron joists for binders are useful, as the floor may be constructed without increasing the depth required by the bridging joists, as shown in fig. 478.

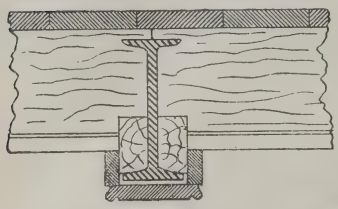

FIG. 479.

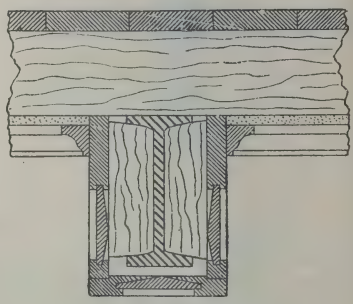

FIG. 480.

Figs. 479 and 480 show rolled-iron joists used as binders, and arranged so as to give the ceiling a panelled appearance.

24	16	14½	13½	12¾	12	11¾
25	16½	15	14	13	12½	12

For ordinary floors up to 16′ span, with the above scantlings, the joists may safely be spaced 12″ apart, instead of centre to centre. For spans over 16′ stiffness requires them 12″ from centre to centre, and over 20′ the scantlings are rather deficient in stiffness.

Ceiling Joists.

2″ thick is sufficient. They are nailed and notched to the joists.

Rule for Depth of Ceiling Joists.

L = length ; *b* = breadth ; *d* = depth.

If $b = 2''$, then $d = \frac{1}{2}''$ for each foot run of span $= \frac{L}{\sqrt[3]{b}} \times \cdot 64$ for fir ; $\times \cdot 67$ for oak.

CEILING JOISTS OF BALTIC YELLOW FIR,
12″ from centre to centre.

14	8	7½	7	6¾	6½	6⅜	6¼
15	8½	7⅞	7½	7⅜	7¼	7	6¾

(*Tredgold.*)

Ceiling joists should never have very long bearings, particularly those for ceilings next the roof of a house, as long joists are subject to warp, which breaks the plastering.

The distance from centre to centre should never exceed 12″, otherwise the bearing for the laths becomes too long. If the distance from centre to centre exceeds 12″, double laths should be used.

Lintels.

Lintels over doors and windows are of wood, generally 1″ in depth for every foot of span in width, or = $\frac{1}{12}$ span; the weight of the wall above being taken off them by a relieving arch of brick or stone of span equal to their full length. If, as for very cheap and temporary work, no relieving arch is used, they should have a depth of 1¼″ to 1½″ for every foot of span, or more if part of the weight of a floor or roof falls over them. The ends should bear 9″ on the wall, although sometimes only given 4½″.

Details of Flooring Boards.

Thickness of Flooring Boards.—1¼″ in ordinary houses.

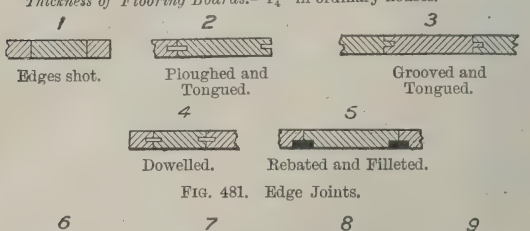

FIG. 481. Edge Joints.

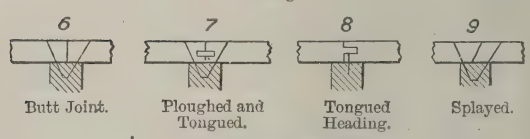

FIG. 482. Heading Joints.

Edge Joints (fig. 481.)—1 is used for inferior floors; 2 and 3 for ordinary floors of a high class; 4 for very superior floors; 5 where the traffic is heavy.

Tongues and Fillets are of wood or hoop iron; the latter, if for good work, should be galvanised. If of wood, should be ¼″ thick, cut across the grain; for strength as well as to prevent splitting, cross or feather tongues are used, the grain running at an angle across the tongue. Iron tongues for 1¼″ boards are 1⅝″ wide, 17 B.W.G.; for 1½″ boards, 1⅞″ wide, of 17 B.W.G.; for 2″ boards 1⅞″ wide, of 15 B.W.G.; for 2½″ and 3″ boards, 1½″ wide, of 15 B.W.G. Tongues are put one-third of depth from bottom of board to give more wear to the upper edges.

Heading Joints.—Fig. 482 shows various forms of heading joints, the inclined black lines being the securing nails.

Secret Joints.

Joints for important or polished floors are secured in such a manner as not to show their fixing, or present gaps or unsightly holes, as would occur in ordinarily fixed flooring, and as they are all fixed on one edge only, are free to shrink or swell without splitting.

Figs. 483, 484, show boards secured by dowel pins and screwed to joists through one edge only, a cheap and effective method, but one which does not prevent dust passing through.

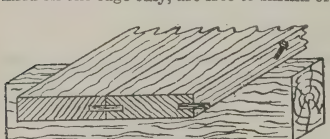

FIG. 483.

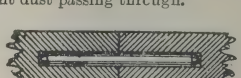

FIG. 484.

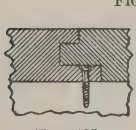

FIG. 485.

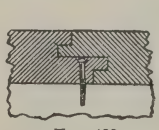

FIG. 486.

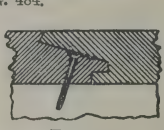

FIG. 487.

Figs. 485 and 486 show the method by rebate, groove and tongue, secured by screws on one edge only. These can be easily fixed or taken up when required, and prevent any dust passing through. The expense of these joints is the great objection to their use. The method shown in fig. 487 possesses the advantages of the two previous joints at a less cost.

Clasp nails or wrought or cut *flooring brads* are used, two to each board, over each joist. The nails should be from 2″ to 2¼″ longer than thickness of board; 3¾″ (32 lbs. to the 1,000) may be used for 1½″ boarding.

Nail heads, for good work, should be punched down, and the holes stopped with lead putty.

Width of Floor Boards.—For important rooms, 4½″; in ordinary rooms, 7″; for common and

temporary purposes, 9″. The narrower the boards, the less they shrink. All the boards should be *listed*, or have the sapwood removed from edges. They should be very well seasoned; if not, they should be temporarily laid, and left a year before being finally laid and nailed down.

Ventilation of Floor Joists, &c.

The spaces between the timbers of floors and flat roofs should be well ventilated by air bricks in walls. Ground below a floor should be thoroughly drained, and covered in some cases with a layer of lime concrete, or with ashes and quicklime.

Fire-Resisting Floors.

FIG. 488.

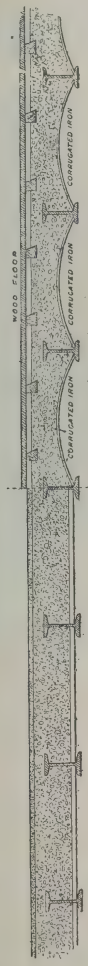

FIG. 489.

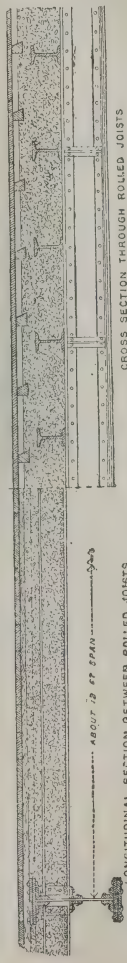

FIG. 490.

FIG. 491.

Expanded Metal.

Expanded Metal as manufactured by *The Expanded Metal Co. Ltd.* (of London and West Hartlepool) is made from sheets of rolled metal, cut and expanded into meshes of various shapes and sizes. Each size of mesh is made in several weights. Each different style and weight has a reference number assigned to it, and may be ordered under such numbers.

Expanded Metal Lathings for Plasterwork.

Expanded Metal Lathings are made from mild steel sheets. They form an ideal key for plaster in ceilings, steelwork encasing, solid and hollow partitions, exterior walls, and other plasterwork. The latest type is known under the trade name of 'BB' Expanded Metal Lathing. All lathing is coated with a mineral oil in process of manufacture, and is dipped once in asphaltum paint at the works. Unpainted lathing is not recommended for plasterwork, and it is advisable to paint all clips, hangers, ceiling bars, etc., as well as the lathings.

'BB' Expanded Metal Lathing supersedes the older types: all are suitable for hair plaster, but the 'BB' and ½-in. meshes are preferable for hairless plaster. The 'BB' and Diamond Mesh Lathings are suitable for all purposes to which metal lathing can be applied; but the Cup Mesh Lathing is not recommended for curved or bent work: all may be used for steelwork encasing. For special ceilings, heavy ornamental plasterwork, heavy facing such as tiling, mosaic, etc., and for exterior work, the heavier lathings should be used, especially in horizontal work.

Expanded Steel Reinforcement for Concrete.

Expanded steel sheets and bars, which are made from mild steel, are specially suitable for reinforcing concrete in foundations, roads, walls, floors, roofs, beams, columns, lintels, arches, bridges, silos, coal pockets, tanks, reservoirs, dams, retaining walls, piers, abutments, pipes, sewers, conduits, etc. Diamond Mesh Expanded Steel of the 3-in. mesh weights is most commonly used for such work, and the 1½-in. and 6-in. meshes may also be used in some cases; the lighter weights of the ¾-in. and 1½-in. meshes are frequently used in concrete for encasing steelwork. Expanded steel, as reinforcement for concrete, has exceptional qualities; it is supplied in flat sheets ready for use, packs closely, and is easily transported and quickly handled. It is simple, economical, and effective. Its total area is available for reinforcement, and it gives a good bond. Being machine made and of meshwork formation, there are no loose strands, the junctions between the meshes being formed and remaining uncut during the process of manufacture. Thus the strands or members are all rigidly connected, and have continuous fibres. The meshes key into each other, and consequently interlock where the sheets overlap at joints. A perfect mechanical as well as cross bond is obtained, for, owing to its rigidly-spaced diagonal meshwork formation, the reinforcement cannot slip within the concrete.

Expanded Steel Reinforcement for Brickwork.

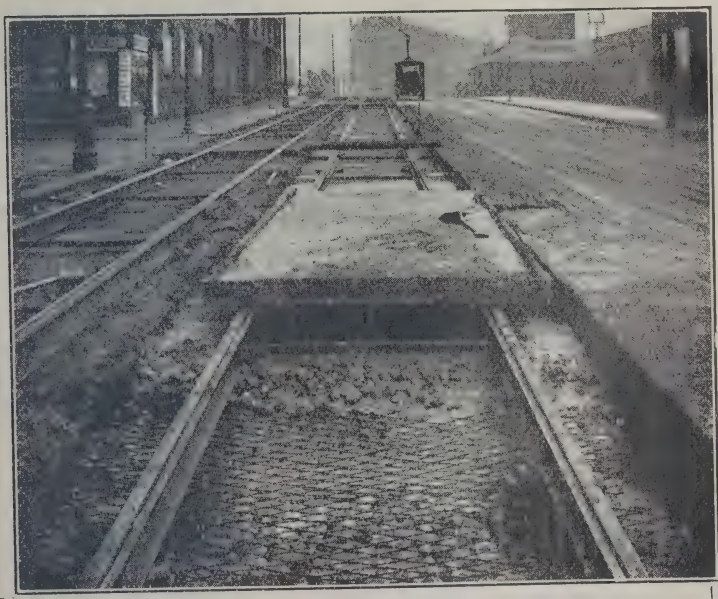
'Exmet' reinforcement for brickwork is specially suitable for reinforcing brickwork, concrete slab constructions, partition slabs, asphalt, etc. It is manufactured from 24, 22 and 20 gauge mild steel, in 2½-in., 7-in., and 12-in. widths, and is supplied in standard coils containing 270 or 75 feet lineal, dipped once in asphaltum paint at the works.

Expanded Metal made-up Goods.

Practically any of the meshes may be used for openwork partitions, shop divisions, fencing, etc.; guards for machinery, windows, trees, etc.; lockers for clothes, tools, etc.; baskets for letters, waste-paper, etc.; and similar articles.

Expanded Metal Lathing and Plaster Partitions.

These are constructed solid or hollow according to requirements.



The weight per super foot of surface area, measured one side only, is for 2-in. solid walling about 18 lbs.; and for 6-in. hollow walling about 21 lbs., with a slight increase in weight if the outside skin is back-plastered.

The lighter lathings may be used for both systems, but the heavier lathings are recommended for exterior work.

Solid Partitions, etc.—The metal grounds for solid partitions, etc., are formed of Expanded Metal Lathing securely fastened to ⅜-in. diameter, or other suitable rods, placed vertically 12 ins. to 15 ins. apart. Tension rods are fixed tautly at their ends with screws to timber, hangers or spikes to concrete, and clips to steelwork.

When the metal groundwork is completed it must be temporarily strutted and railed at half height on one side to keep it in a vertical plane. The first or 'render' coat should then be applied on the opposite side, ½ in. thick, and allowed to set hard previous to the second coat being applied. When these two coats are set the temporary supports may be removed, and the reverse side floated. The finishing coat is then applied in the ordinary way. Interior solid partitions are sometimes built only 1½ in. thick, but usually they are made 2 ins. thick; exterior solid walls are generally made 2¼ ins. to 3 ins. thick.

EXPANDED METAL SUSPENDED CEILINGS.

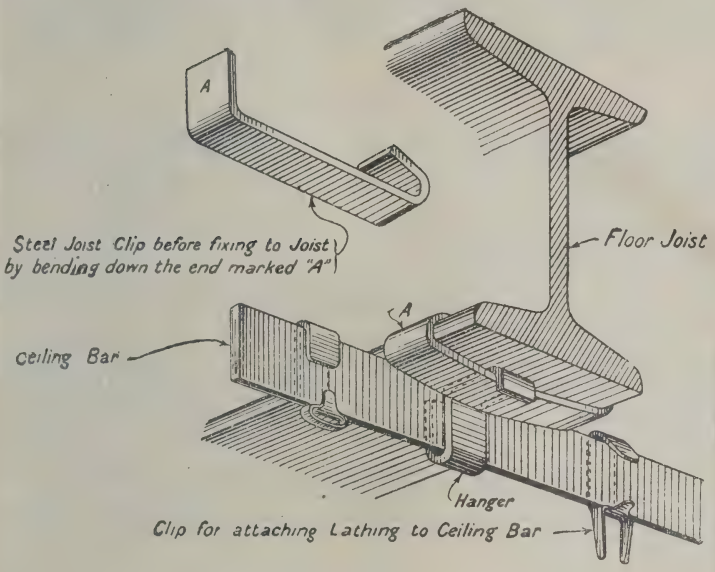

FIG. 491A.

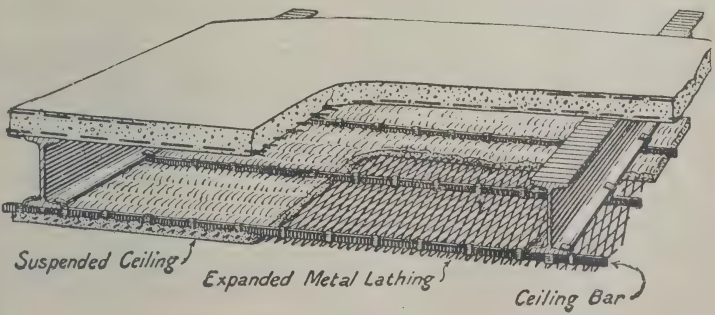

FIG. 491B.

Hollow Partitions, etc.—The metal grounds for hollow partitions, etc., are formed of Expanded Metal Lathing, securely fastened on both sides to steel studs spaced from 12 ins. to 15 ins. apart. These studs are formed of two angle bars, connected by distance straps, having also foot and head pieces, which are holed to allow of the studs being fixed to concrete flooring with spikes or to wood flooring with screws. If the studs have to be fixed to steelwork a clip is riveted to the foot and head pieces to form means of attachment. Another and cheaper form of stud is the rib stud, made from Rib-Mesh Expanded Steel. Overall thickness is regulated by the length of the connecting spacers; 6 ins. is a usual overall dimension, and a $\frac{3}{4}$ in. skin of plaster is sufficient for interior work, and a $1\frac{1}{4}$ in. skin for exterior work. It is wise to back-plaster lathing in exterior work and thus embed it.

Suspended Ceilings.

These ceilings (figs. 491A and 491B) can be suspended at any desired level and to any desired shape. They may be fixed flush with the soffits of floor joists, roof principals, etc., or they can be suspended below them at suitable distance to accommodate pipes, electric wires, etc. The ceilings may be carried to the side walls, in bays or coves of any desired form, for obtaining artistic or decorative effects.

A flat ceiling with hangers varying in length, or a curved ceiling with hangers made to follow the contour, may be suspended below arched flooring, etc.; ceilings suspended from roof principals may be dealt with in the same manner.

For spans of up to 10 feet, flat mild steel bars, of suitable section, are suspended on edge from the joists, etc., at intervals according to the weight of lathing to be used, by means of mild steel hangers specially made for the purpose.

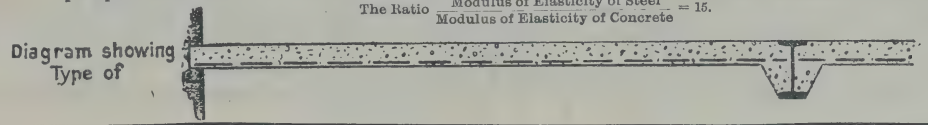
Where bars join they should overlap, at least 2 ins., in a hanger. In wall-end bays the bars should be pinned not less than 2 inches into the masonry. In long spans it is wise, at the half-span, to tie a bearer bar on top of and at right angles to those on edge, to maintain them in a vertical plane. The hangers are secured by screws to timber joists; attached to R.S.J.'s by means of mild-steel clips; bent over tie members of roof trusses, and pinned into reinforced concrete beams. The bars should be wired down to the hangers and at lapped joints to prevent the metal grounds from rising.

The lathing is then fixed to the ceiling bars with lathing clips or with galvanised soft iron wire, and when this is completed the ceiling grounds are ready to receive plaster.

The weight of these suspended ceilings, including metal grounds and plaster, ranges from 9 to 12 lbs. per foot super; and the air space provided affords a perfect fire and sound resisting construction.

Steelwork Encasing.

For plaster work, the lathings, and sometimes the lighter weights in $\frac{3}{4}$ in. mesh, such as No. 38, are used; while for concrete encasing, formed with temporary centering, the lighter weights in $1\frac{1}{2}$ in. mesh, such as No. 6, are recommended.



Structural Steelwork Encasings.—In many cases lathing is simply wrapped or bent round the steelwork, secured in position when necessary, and tied together at lapped joints with galvanised soft iron wire, and then covered with plaster. A better system, however, is to use some form of metal cradling, such as $\frac{1}{2}$ in. or $\frac{3}{8}$ in. round rods, bent to the shape of the steelwork, and secured in position, to which to tie the lathing. In high-class work, the encasing round the steelwork should not be less than 2 ins. thick, and should be in one body; this thickness can be best obtained in the following ways:—for plaster finish, by fixing the lathing 2 ins. from the face of the steelwork, filling in the space with concrete, and covering the lathing on the outside with plaster; for concrete finish, by using temporary centering and placing $1\frac{1}{2}$ in. mesh Expanded Metal in the centre of the 2 in. of concrete.

Girder Encasing.—For boxing-in exposed girders, etc., not more than 12 ins. on side or soffit, Expanded Metal Lathing can be wrapped round the beam and secured by staples, tenter hooks, or spikes to the underside of the floor above, or preferably wired to $\frac{3}{8}$ in. round rod cradling fixed at 12 in. to 15 in. centres along the beam. In the first system the long way of the mesh in the lathing should be vertical on the sides and in the second it should be horizontal. For larger section beams the second system should always be used.

Wall Casing or Covering, which is sometimes called deafening, is constructed by means of hold-fasts set into the wall at about 4 ft. centres vertically, and spaced horizontally according to the weight of the lathing to be used. These hold-fasts are holed or hooked at their outer end, and flat bars are either bolted or wired vertically in position, the lathing and plaster being applied as described elsewhere.

These Tables are based on a mixture of Concrete of not less than 4—2—1 by volume; a working stress not exceeding 16,000 lbs. per square inch tension in the Expanded Steel, and 500 lbs. per square inch extreme surface compression in the Concrete.

The Ratio $\frac{\text{Modulus of Elasticity of Steel}}{\text{Modulus of Elasticity of Concrete}} = 15.$

Safe Working Loads per Foot Sup. Supported Slabs. B.M. $= \frac{WL}{8}$.

Note.—Generally it is not economical to use thicknesses shown below the zigzag line in the table.

The following mixtures of concrete, all parts by measure, are recommended for use with Expanded Steel reinforcement :- *For floors, walls, etc., up to 3½ ins. thick :* 3 parts of aggregate, 1½ parts of sand, to 1 part of Portland cement ; *thicker than 3½ ins. :* 4 parts of aggregate, 2 parts of sand, to 1 part of Portland cement. *For general concrete work such as foundations and heavy work :* 5 parts of aggregate, 2½ parts of sand, to 1 part of Portland cement. *For concrete to retain liquid pressures :* 3 parts of aggregate, 2 parts of sand, to 1 part of Portland cement. The aggregate should be clean sharp broken flint gravel, or hard and durable broken stone. For steelwork encasing, flooring and similar work, if such aggregates are not readily obtainable hard broken brick or hard furnace clinker, or a mixture of the two, free from combustible materials, old mortar, ashes and dust, may be used. Cinders and coke breeze are not recommended for reinforced concrete work. The aggregate should be of various sizes between ¼ in. and ¾ in. for the 4½, 5 and 6—1 mixtures, and from 1½ in. to ¼ in. for the 7½—1 mixture, all fine stuff below ¼ in. may be used in place of sand. The sand should be clean sharp gritty sand consisting of mixed or graded sized grains from ¼ in. down with the coarse grains predominating. Portland cement must be used and it should be in accordance with the requirements of the current British Standard Specification. The concrete should be mixed three times dry and three times after water has been added and must be deposited before the cement has reached its initial set and must not afterwards be disturbed.

(The Expanded Metal Co. Ltd.)

Air-Ducts, False Beams, Cornices, Pillars, Pilasters, etc., can be constructed by means of light steel framework fixed to receive the lathing, and if the cradles cannot be placed sufficiently near each other themselves to take the lathing, $\frac{3}{8}$ in. diam. alignment rods should be wired to the cradles, horizontally or vertically, as the case may be, to form backing for the lathing as well as stiffeners for the cradles.

Expanded Steel Concrete Pipes, Conduits, Sewers, etc., built in situ.

The sheets can be cambered either long way or short way of mesh to suit any requirements. The diagonals of the meshes should run one with, and the other at right angles to, the periphery of the pipe. The reinforcement should not only be laid, but it should also be fixed in place, so that there may be no possibility of its losing its correct position ; it is advisable to clip or wire the sheets together at overlapped joints, and for pressure pipes to allow an overlap of not less than two meshes.

With particular regard to pressure pipes, the concrete forming the main shell should not be depended upon for impermeability, for experience has shown that the tamping seams are to be feared, no matter how carefully fresh material may be added to that which has already been laid.

For pressures of up to 50 feet, a $\frac{3}{4}$-inch facing of cement and sand 1 and 2, laid in one body on the centering immediately before the concrete or on the concrete after the removal of the forms, has proved effective. But for greater pressures the facing should be laminated or put on in coats, the first coat not less than $\frac{1}{2}$-inch of cement and sand 1 to 2 ; the second of about $\frac{1}{4}$-inch, 1 to 1, trowelled to a hard polished surface, and a final wash of thick grout.

Generally speaking, the thickness of the concrete shell should in no place be less than one-twelfth of the greatest internal diameter of the pipe, with an allowance of 1 in. for cover to the reinforcement, whilst the steel should be designed to resist the whole of the tensile stress.

Fire-Resisting Materials.

The best materials to resist fire are brickwork, burnt clay in any form, plaster, and concrete.

Girders and Arches form a heavy floor ; the girders may be protected by blocks of fireclay, or plaster, or concrete. Fire-brick arches 4′ to 12′ span, spandrels filled in and backed up with concrete, or arches may be of concrete only.

Figs. 488 to 491 (page 343) show various forms of fireproof floors. The concrete in some cases is made of calcined gypsum, which does not lose its cohesive power even when raised to a white heat and drenched.

The American Concrete Institute recommends that for fire-resistive construction, limestone, trap rock, blast-furnace slag, and burned clay be given a preference over highly siliceous gravels ; that in cases where gravel aggregate is to be used, with no additional protective material over the concrete, round columns be given a preference over rectangular ones ; and that where gravel aggregate is used all columns, but especially rectangular columns and round columns with spiral reinforcement, be given the additional protection of approximately 1 in. of Portland cement plaster either on metal lath or reinforced by light expanded metal.

Bracket.

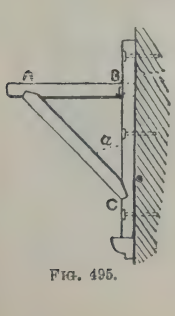

FIG. 495.

If a weight, W, is placed at point A, fig. 495, tension tending to pull bracket out of socket at B

$$= W \tan \alpha = W \frac{AB}{OB}.$$

Compression on $AC = \frac{W}{\cos \alpha} = W \frac{AC}{BC}$. If W is distributed over AB, these strains will be $\frac{1}{2}$ W tan α and $\frac{1}{2} \frac{W}{\cos \alpha}$; and there will be a maximum bending moment on $AB = \frac{W \times AB}{8}$, which is lessened by the tensile stress $\frac{1}{2}$ W tan α, tending to prevent bending and to draw it out at B.

Vertical strain on BC = W.

Partitions.

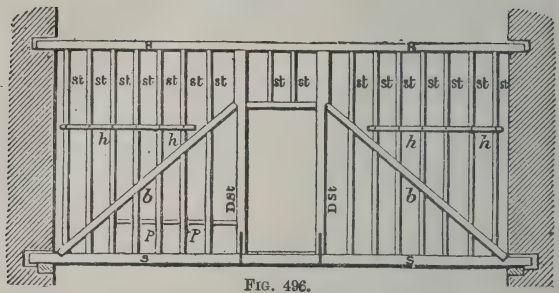

FIG. 496.

Partitions (fig. 496) should be framed so as to be supported only by the walls. *b* braces, H head, S sill, *st* studs, D*st* door-studs.

Dimensions of principal timbers, *b*, H, D*st* :—

4″ × 3″	for a bearing not exceeding	20	feet.
5″ × 3½″	„	„	„	30	„
6′ × 4″	„	„	„	40	„

The filling-in pieces, 'studs,' or 'quarterings,' need not be thicker than 2″, or just sufficient to nail the laths to. They are tenoned to the top and bottom plates, but butted and nailed on to the braces. If they exceed 3′ or 4′ in length they should be strengthened by short struts or horizontal pieces, as at *p*, *p*, called 'nogging pieces,' or, what is better, by a continued rail, *h h*, notched across the uprights and nailed to each. In a brick nogged partition the nogging pieces are essential. They are much thinner than in a lath-and-plaster partition, being about ¾″ thick and 2″ wide, placed at every fourth course of the brickwork in height.

The studs or quarterings for a lath-and-plaster partition should be spaced at from 12″ to 18″ from centre to centre ; in a brick nogged partition they should be 18″, 2′ 3″, or 3′ apart. If a partition is not well framed, or is made with unseasoned timber, the plastering will crack. Weight of a square (100 feet super) of partitioning may be taken at 1,480 to 2,000 lbs.

Slag Wool, packed in the full depth of the joists between ceiling and floors, is an effective deadener of sound, and this method has the advantage of leaving no hollow spaces in which vermin can congregate, or in which fire can work its way unseen. Strips of hair felt should be laid along the joists to prevent continuity of woodwork, otherwise sound will be transmitted through the woodwork itself. The approximate quantity of slag wool required to fill a square yard of flooring, say 9 inches deep, will be 80 lbs., of which the approximate cost is 3*s*. This method is perhaps a little more costly than some architects care to adopt, and lesser thicknesses of slag wool produce very satisfactory results.

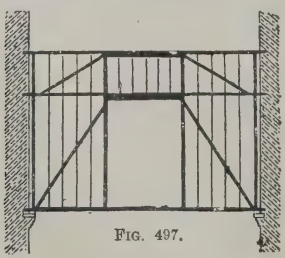

FIG. 497.

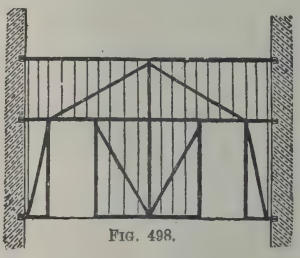

FIG. 498.

Figs. 497 and 498 show arrangements for partitions having doorways ; in both cases the main portion of the partition is suspended from the truss forming the upper part of it (*Tredgold*).

For rendering partitions, as far as possible, sound-proof, 'Willesden Paper' (*The Willesden Paper and Canvas Wo·ks, Ltd*) may be used with advantage ; it is also damp-proof.

Stairs.

Stairs (fig. 499) are described according to their form in plan, viz. :—

1. *Straight—a.*

2. *Dog-legged—b* ; when the flights rise alternately in opposite directions with no interval between the flights.

3. *Open newel—c* ; when the flights are ranged round an open well-hole, with a newel post at each angle.

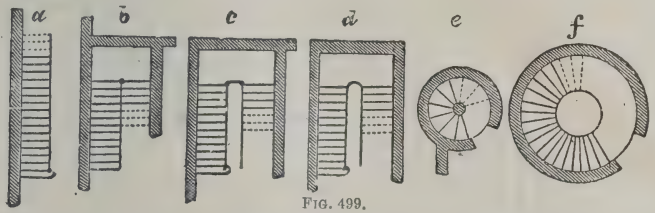

FIG. 499.

4. *Geometrical—d* ; similar to the last but with no newel posts ; the handrail running uninterruptedly from bottom to top. The angles of the well-hole are generally rounded.

5. *Circular newel—e.*

6. *Circular geometrical—f* ; when without a central newel.

Width—Stairs should be 3′ 6″ wide to allow two persons to pass easily.

Tread and Rise.—Tread should be from 9″ to 12″, rise from 6″ to 7½″. Tread increases as rise decreases. The following rules are in use for proportioning rise and tread of steps :—

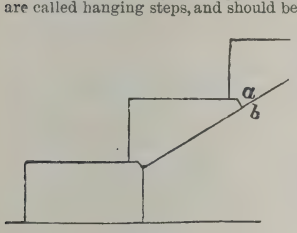
1st. Tread in inches + twice rise in inches = 24. 2nd. Tread × rise = 66.

Flights.—It is dangerous to have a stair between two floors in one continuous flight. Considering convenience and effect, it is desirable to limit height of one flight to about 7′, and to avoid having two flights in one direction. *Winders* should be avoided if possible.

Handrail.—Upper surface should be from 2′ 7″ to 2′ 9″ above the surface of the tread at the nosings, and on landings from 3′ to 3′ 3″. Or, taking the height at landings as 3′ subtract ½ the rise for height of rail from nosings of steps.

Materials.—In lofty dwellings it is desirable that stairs should be of stone or concrete to be fireproof, at any rate in the lower storeys.

Stone Stairs.—Steps are supported by a wall at one or both sides. When at one side only they are called hanging steps, and should be built at least 9″ into the wall. The bottom step is bedded on the floor, and the lower front edge of each other step rests on the upper back edge of the step below. The best form for the joint is shown in fig. 500, where the face *ab* is at right angles to the general inclination of the stair, and about 1″ wide. Spandrel steps should have the sides which are built into the wall left square.



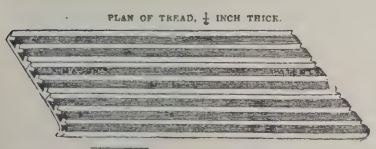


FIG. 500.

Repairing Stone Steps when Worn.—One plan is to fill up the hollows with Portland cement concrete made with fine sharp washed gravel about the size of a pea, 1 part gravel, 1 part cement. The worn part should be chiselled down, so as to give at least ⅜″ thickness of concrete in every part. The edge of concrete steps should always be rounded. Another method is to insert and cement slabs of artificial stone instead of concrete ; the stone known as the 'Silex' brand is very suitable for the purpose.

Lines thus ▬▬ *represent Lead—other parts Chilled Steel, Brass, or other Hardened Metals.*

FIG. 500A.

MASON'S TREADS.

(*Patent.*)

These treads, fig. 500A, which have remarkable unwearable and non-slipping qualities, are adapted to either wood or stone stairs. The arrangement is such that a hard metal withstands the wear, and a soft one gives the foothold.

Wooden Stairs.—Fig. 501.—Treads should be of hard wood, $1\frac{1}{8}$" thick, for steps 4' long, increasing $\frac{1}{8}$" for every additional 6" of length.

The treads and risers are supported by a wall string and an outer string, the former $1\frac{1}{2}$" thick, the latter 2". Treads and risers are housed into the wall string, and secured by wedges.

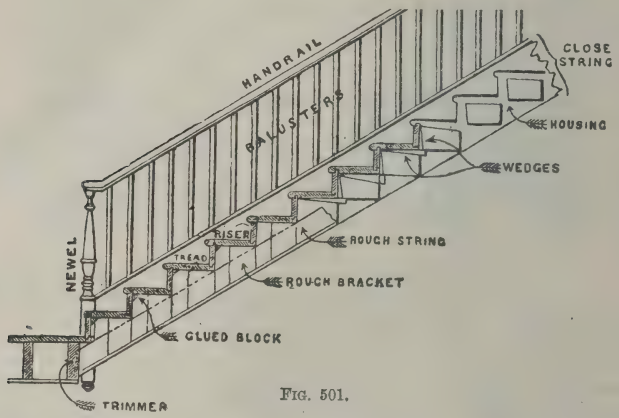

FIG. 501.

The outer ends may be either housed into a close string, or may rest on and be mitred to the notches of an open string.

When stairs are more than 3 ft. wide, treads should be supported by rough strings or carriages fixed underneath and framed into the trimming joists of the landings. Scantlings of rough strings are calculated as bridging joists. Rough brackets are nailed to the side of the rough string to support the treads.

Joints between treads and risers are grooved and tongued, feathered or rebated. The last is the best joint.

'ÆGIS' ASBESTOS-CEMENT BUILDING SHEETS.

8' × 4' or 4' × 4'

These sheets (*Turner Brothers Asbestos Co. Ltd., Rochdale*) are readily worked and quickly fixed with ordinary carpenters' tools.

Ceilings.—For ceilings, sheets $\frac{5}{32}$ in. or $\frac{3}{16}$ in. thick are most suitable, and are nailed to ceiling joists with $1\frac{1}{4}$-in. galvanised or copper nails at not less than $\frac{1}{2}$ in. from edge of sheets, and about 6-in. centres, care being taken that edges butt closely and nail heads are flush.

In forming ceilings, 4-ft. by 4-ft. sheets are recommended. These are quickly and easily handled by the erectors, and the ceilings may be subdivided into panels, the joints being covered with a moulded wood or fillet strip, the result giving a highly decorative effect.

Partitions.—These may be formed with sheets $\frac{3}{16}$ in. to $\frac{1}{2}$ in. thick, nailed as before described to timber studding, spaced at 1 ft. 4 in. or 2 ft. centres. Between the standards, dwangs or struts should be placed to support the ends of the sheets. The joints may be filled before painting, and the whole surface rubbed down in the usual way, or as an alternative covered with moulded wood or fillet strips.

For 'Turners' Roofing Slates,' see p. 411.

BUILDING MATERIALS AND CONSTRUCTION.

PART I

TIMBER—SEASONING—CREOSOTING—WOODEN PILLARS—ROOFS—BRICKWORK—WALLS—LONDON BUILDING ACTS—FOUNDATIONS—MASONRY.

TIMBER.

(Contributed by Alexander L. Howard.)

In all specifications for building materials and construction, it is customary to use the terms 'Timbering,' 'Joiners' work,' and 'Cabinet work.' The first-named applies only to the wood used in constructional work. These terms are again subdivided into the following :—

Baulks.—Small-sized squares up to 9 ins.

Timber.—Includes everything, whether hewn or sawn, above the size of baulks.

Planks.—Includes everything above 1½ ins. in thickness, and more than 9 ins. in width.

Deals.—Confined entirely to widths of 9 ins. of thicknesses above 1½ ins. Thicknesses less than this are termed deal boards.

Battens.—Includes any thickness above 1½ ins., and over 4 and under 9 ins. in width.

Boards.—Includes everything, whatever the width, of 1½ ins. in thickness and under.

Scantlings.—An inclusive term which covers the whole of the requirements with the exception of prepared floorings, skirting or joiners' work, but which is generally used more particularly to describe small-sized pieces which are not named specifically above, such as 3 ins. × 4 ins., 2½ ins. × 3 ins., etc.

Lumber.—The term used in Canada and the United States for sawn wood of all descriptions.

It is customary in some specifications to require that the boards shall be of deal widths or of batten widths. In such case the above limitations are observed.

For scaffolding, etc., round timber is described by the following terms :—

Scaffold poles.—These range in size from 2½ to 6 ins. in diameter in the middle.

Spars.—Above 6 ins. in diameter in the middle.

Rickers.—Sizes less than the above.

In specifying thicknesses and widths it is customary, except in the case of Government contracts, to accept these after planing ; thus, where 1-in. thickness is specified, the completed work is ⅞ ins. in thickness, while a width of 12 ins. should actually finish a full 11¾ ins.

Timber Measures.

BAULKS AND TIMBER.—Sold at per load of 50 ft. cube. Deals, planks, battens and scantlings at per Petrograd standard. (One standard = 165 ft. cube.)

PREPARED FLOOR BOARDS.—These are usually sold at per square. This is a standard measurement which equals 100 ft. superficial. Till recently it was the trade custom to supply a specific number of feet, according to the width of the board, which should approximate to the square. These were as follows :—

4-in. boards	. . .	300 ft.	
4½	„ . . .	270	„
5	„ . . .	240	„
5½	„ . . .	220	„
6-in. boards	. . .	200 ft.	
6½	„ . . .	190	„
7	„ . . .	180	„

This practice, which was always unsatisfactory owing to the inaccuracy of the figures, has now been discontinued.

LUMBER (see above) AND AUSTRALIAN WOOD.—Sold at per 1,000 ft. of 1-in. superficial measure for all thicknesses of 1 in. and over. Under 1 in. at per 1,000 ft. superficial of their thicknesses. Teak at per load of 50 cub. ft.

Descriptions of Soft Woods.

PINE, SCOTS (*Pinus sylvestris*, Linn.).—Commonly called 'red' or 'yellow,' 'red' or 'yellow fir,' 'yellow deal,' 'deal.' Used for joists, floors, roofs, sash-frames, sashes, doors, centering, scaffolding, piles, etc., that is, for all timbering work in buildings excepting where baulks or logs hewn or square sawn are necessary. When reasonably free from sap and in bright condition is very durable. Archangel, Onega, Petrograd, and a few of the Swedish ports supply the best quality, but good qualities also come from other districts.

SPRUCE (*Picea excelsa*, Link.).—Commonly called 'white,' 'white fir,' 'white deal,' or 'white battens.' Used in Scotland and the north-west districts generally, for timbering work and for floorings, skirtings, and joiners' work of the cheaper class. In the midlands and south used for the latter purposes, but there usually considered unsuitable for timbering work. When used for boards, skirtings, joiners' work, etc., and properly ventilated, is fairly durable, though not in the same degree as Scots pine. Archangel, Onega, Petrograd, and some Swedish ports supply, as with Scots pine, the best quality, though good timber also comes from other districts.

SPRUCE, CANADIAN AND AMERICAN (*Picea alba*, Link.).—Although used to a certain extent in Scotland and the north-west districts, and occasionally elsewhere, it is not suitable for building construction as it is not durable, nor does it possess a sufficient degree of strength for such work.

LARCH (*Larix europæa*, DC.).—Not commonly used for building construction, though its strength and durability would recommend it equally with Scots pine. Although the supplies of British-grown larch are not ordinarily made use of for such work, yet its good qualities recommend it for more general consideration.

PINE, PITCH (*Pinus palustris*, Mill.).—Commonly used for large timbering sizes, joiners' work and flooring. Not usually employed for ordinary timbering work. Stronger than the descriptions named above, and equally durable, but only when completely ventilated. Should not be used for constructional work when thorough ventilation is impossible. Imported in all sizes and descriptions sawn and hewn square of large sizes and long lengths. Planks, deals, battens and boards are imported in three qualities described as 'prime,' 'unsorted or rio,' and 'merchantable.' In the import of square sawn or hewn timber the further standard of quality is indicated by the terms 'long leaf' or 'short leaf.' It is probable that the best quality only, i.e. 'long leaf,' is the produce of *Pinus palustris*, while that described as 'short-leaf' is the produce of many sorts, including the Loblolly pine (*P. taeda*, Linn.).

PINE, RED CANADIAN (*Pinus rubra*, Mich.).—Used commonly in Scotland and the north-west districts, and only occasionally in the south and the midlands. Generally shipped in lengths of from 10-16 ft., though occasionally in shorter lengths; on this account generally unsuitable for timbering work: also in deal and plank sizes, and small quantities of other scantlings. Similar to Scots pine in appearance, though slightly redder in colour. Excellent in constructional and joiners' work, though for the latter, perhaps, rather hard in texture. Very durable in all situations, but requires good ventilation.

PINE, AMERICAN WHITE (*Pinus strobus*, Linn.).—Known in England as 'yellow pine,' in Scotland as 'white pine,' or 'yellow pine,' but in America always as 'white pine.' Formerly used for joiners' work in England and largely so in Scotland and the north-west districts, but of late years has been too expensive for such uses.

PINE, OREGON (*Pseudotsuga Douglasii*, Carr.).—Known also as 'British Columbian pine,' and 'Douglas fir.' Obtainable in very long lengths and large sizes, very free from knots and generally only carrying a moderate amount of sapwood. Not very favourably received hitherto as it is not considered durable. Mostly used for roofing timbers for public buildings and for floorings; also a restricted amount for joiners' work; for this purpose not much in favour as the hard grain rises or the soft grain sinks, so presenting a ridgy surface under paint or varnish.

Descriptions of Hard Woods.

ACACIA (*Robinia Pseudacacia*, Linn.).—Weight, 51 lbs.* Europe. Golden-yellow. Hard, very durable, especially in contact with the ground, and in alternate wet and dry. When well seasoned is stronger, stiffer, and tougher than oak. Used for sills, wall-plates, posts, palings, trenails for ships. Would be well adapted for decorative cabinet work.

ACAPU (*Andira aubletii*).—Weight, 70 lbs. Brazil. Dark brown, very hard, durable and strong; excellent for flooring and frame-work.

ALDER (*Alnus glutinosa*, Gaert.).—Weight, 30 lbs. Great Britain. Brown; very durable under water, works well and easily. Valuable for piles, planking, sluices, pumps, etc. Used also in turnery and for other light purposes; large quantities also in the form of plywood.

ALMOND WOOD, INDIAN (*Chickrassia tabularis*, Adr. Juss.).—Weight, 49 lbs. India. Yellowish to reddish-brown, with beautiful satiny lustre and fine silver grain. Seasons and works well. Used for furniture and carving.

ANJAN (*Hardwickia binata*, Roxb.).—Weight, 82 lbs. India. Dark-red, streaked with black or purple; cross-grained, extremely durable, very hard; liable to split, does not warp. Excellent for sleepers but difficult to work; used for naves for cart-wheels, and for agricultural implements.

---

* Weights given are average dry weight per cubic foot

(*Anogeissus latifolia*, Wall.).—Weight, 62 lbs. India. Purple-brown, shining, very hard, strong, and tough but liable to split in seasoning. Used in shipbuilding, for axles of carts and also for furniture.

ASH, ENGLISH, CANADIAN AND AMERICAN (*Fraxinus excelsior*, Linn., *F. americana*, Linn. etc.). —Weight, 41–46 lbs. The British Isles and North America. White to brownish-white, sometimes with darker streaks. Easily worked, very flexible ; strong, tough and elastic, therefore well adapted for work exposed to sudden shocks and strains. Not durable unless thoroughly ventilated. Largely used in air-craft construction.

ASH, JAPANESE (*F. mandschurica*, Rupr.).—Weight, 34 lbs. Japan. Not so strong or tough as the English species, although strong enough for many purposes, including carriage building. Takes a high finish ; useful for interior fittings and cabinet work. Liable to shrink more in seasoning than English ash, but stands well when seasoned ; has an average weight of from 12 to 15 per cent. less.

BASSWOOD (*Tilia americana*, Linn.).—Weight, 30 lbs. North America. Pure white to whitish-brown, soft, easily worked, durable after seasoning though liable to shrink in the process. Used for turnery, carpentry and furniture, and is especially useful in the pianoforte trade. Should not be confounded (although it generally is) with canary whitewood (*q.v.*).

BEECH (*Fagus sylvatica*, Linn.).—Weight, 42 lbs. Europe. Light, yellowish-brown, showing when cut on the quarter the silvery flecks of the medullary rays. Hard, close, fine and even-grained. Very durable when submerged, therefore suitable for piling ; used also for machinery, chair-making, tool-handles, turnery, and a great variety of other purposes.

BIRCH (*Betula lenta*, Linn.).—Weight, 48 lbs. Europe and North America. Firm, tough ; works up easily to a satiny lustre. Used for wheelwrights' work and for furniture ; large quantities also for plywood.

(*Bischofia javanica*, Blume).—Weight, 45 lbs. India. Red, tough, moderately hard. Though liable to warp and crack above ground, yet when in wet ground or completely submerged is almost imperishable. Suitable for piling and all constructional work, and for building.

BLACKBUTT (*Eucalyptus pilularis*, Sm.).—Weight, 57 lbs. Australia. Light-brown, heavy and somewhat difficult to work owing to interlocked grain ; very strong and durable. Used in large quantities for street paving and for sleepers ; suitable for all constructional work.

BLACKWOOD, AFRICAN (*Dalbergia Melanoxylon*, Guill. and Perr.).—Weight, 74 lbs. Tropical Africa. Sometimes known as Senegal ebony. Dark-brown to jet-black with slightly fragrant scent. Used in turnery and for musical instruments.

BLACKWOOD, AUSTRALIAN (*Acacia Melanoxylon*, R.Br.).—Weight, 45 lbs. Australia. Dark reddish-brown with a lustrous sheen, often beautifully figured. Easily worked, liable to warp unless thoroughly seasoned, but when seasoned stands exceedingly well under the most trying conditions. Useful for all kinds of construction, carpentry and cabinet work. The figured wood is used in the form of veneer for panelling, etc.

BLACKWOOD, BOMBAY. See Rosewood, Indian.

(*Boehmeria rugulosa*, Wedd.).—Weight, 41 lbs. India. Red, moderately hard, smooth and even-grained ; seasons well and is easily cut. A splendid wood for carving ; suitable for turnery.

BOXWOOD (*Buxus sempervirens*, Linn.).—Weight, 30 to 60 lbs. Europe, Asia Minor, etc. Exceedingly hard, very dense and close in the grain. Cuts well without splintering ; susceptible of a fine polish ; liable to split unless carefully and thoroughly seasoned. Used largely for blocks for wood-engraving, also in turnery, for instruments for sports and games, etc., and for a great variety of other purposes.

BOXWOOD, KNYSNA, OR EAST LONDON (*Gonioma Kamassi*, E. Mey.).—Weight, 58 lbs. South Africa. Uses as above.

(*Calophyllum spectabile*, Willd.).—Weight, 38 lbs. India and Ceylon. Shining, light-red, cross-grained ; squares up to 25 ft., siding 18 ins. Used for masts, spars and planking.

CAMPHORWOOD (*Cinnamomum camphora*, Nees.).—Japan. A medium-grained, fragrant, cinnamon-coloured wood. Used for the linings of drawers and cabinets.

CAMPHORWOOD, BORNEO, or KAPOR (*Dryobalanops aromatica*, Gaert.).—Weight, 47 lbs. Malay Peninsula. Straight-grained, hard, tough, and durable. Used for heavy constructional work, planks, beams, piles, etc., and for joiners' work and shipbuilding.

CEDAR.—A name given erroneously to many species of *Juniperus* and *Cedrela*, etc. True cedars are the Himalayan (Deodar), Atlantic and Lebanon cedars.

CEDAR, CIGAR BOX (*Cedrela odorata*, Linn.).—Weight, 30 lbs. Tropical America. Also known as West Indian cedar. A soft, red, fragrant wood ; used as its name implies.

CEDAR, MOULMEIN (*Cedrela Toona*, Roxb.).—Weight, 30 lbs. India. Warm red, durable and easy to work. Used for cabinet-making, furniture, cigar boxes and carving.

CEDAR, PENCIL (*Juniperus virginiana*, Linn.).—Alternatively known as red cedar and Virginian cedar. Weight, 30 lbs. United States. Light, soft and fine-grained. Very durable, especially in contact with the soil. Used chiefly for pencil-making ; also employed, though to a limited extent, for cabinet work and panelling.

CHAPLASH (*Artocarpus Chaplasha*, Roxb.).—Weight, 34 lbs. India. Yellow to brown, even-grained ; seasons well and is durable. Suitable for building and joiners' work ; also for furniture.

CHESTNUT (*Castanea vesca*, Gaert.).—Weight, 30-40 lbs. Europe. Commonly called 'Sweet Chestnut,' or 'Spanish Chestnut.' Light to dark brown ; resembles oak, from which it is only distinguished by the absence of the pronounced medullary ray so evident in that timber, A very valuable wood, insufficiently appreciated. Easier to work than oak, although more tough,

not so strong or stiff. Very durable in water when wholly submerged, or in outdoor work where ventilated, and in joiners', cabinet and panelling work. Does not shrink or swell much; gives way suddenly under cross-strains. Used in the past for roof timbers and panelling; often mixed with oak (a very intelligent manner of use, as, unlike oak, insects, fungus, wood-boring beetles, etc., dislike it, so that its use mixed with oak has helped to preserve the latter from such attacks). Also largely employed for fencing, posts and rails, hop-poles and furniture. Large-sized trees are much spoilt by spiral growth and cup and heart shakes, suggesting careless forestry during growth.

CHESTNUT, HORSE (*Aesculus hippocastanum*, Linn.).—Weight, 30 lbs. Europe. Yellowish-white, soft, and not very durable. Used for rollers in cotton mills.

COCOBOLO.—Weight, 70 lbs. South America. A handsome, rich dark-red wood streaked with black or orange; hard, strong and durable. Used chiefly in the form of veneer for decorative work, such as brush backs, handles, and turnery.

COCOBOLO, INDIAN (*Dalbergia cultrata*, Grah.).—Weight, 70 lbs. Burma. Dark red to purple, streaked with black; very hard. Uses as above.

COCUS-WOOD (*Brya ebenus*, DC.).—Weight, 70 lbs. The West Indies. Dark bronze to brown or purple; very heavy, fine and even-grained, durable. Used for musical instruments and general turnery.

COROMANDEL or CALAMANDER-WOOD (*Diospyros quaesita*, Thw.).—Weight, 57 lbs. Ceylon. Greyish-brown streaked with black. A most valuable ornamental wood, in demand for cabinet work.

CUTCH or KHAIR (*Acacia Catechu*, Willd.).—Weight, 65 lbs. India. A hard wood, varying from light to dark red; seasons well, takes a fine polish and is durable. Employed in house-building, wheelwrights' work and for agricultural implements.

DILO (*Calophyllum inophyllum*, Linn.).—Weight, 42 lbs. India and Burma. Sometimes known as the Alexandrian laurel. Reddish-brown, close-grained. Used in India for such work as shipbuilding, machinery and masts, but would be excellent for cabinet-making.

EBONY (*Diospyros ebenum*, Koenig, etc.).—Weight, 60–80 lbs. India, Ceylon, Africa. Ebonies vary in their degree of blackness, few are jet black; all, however, are heavy, hard and close-grained, and generally durable. Often used in the form of veneer for decorative cabinet work; also employed for inlay and turnery.

ELM, ENGLISH AND AMERICAN (*Ulmus campestris*, Linn., *U. americana*, Linn., etc.).—Weight, 40 lbs. Europe, N. America. Dark-brown, tough, twisted in grain, and therefore difficult to work. Durable both when completely submerged, as in piles, and when perfectly dry, but soon rots when exposed to alternate wet and dry. Warps and twists in seasoning and shrinks very much, but is not liable to split; takes nails well; not so strong, stiff, or tough, as oak. Used largely for piles, water-pipes, pumps, etc., also for coffins, agricultural tools, naves of wheels, sheaves of blocks, keels of ships, and also for chair-making.

ELM, ROCK (*Ulmus racemosa*, Thomas).—Weight, 45 lbs. Canada and the United States. Light yellowish-brown, becoming paler on exposure. Tough, elastic, very strong; durable when submerged or when thoroughly ventilated. Used for boat and ship building, ladders for ships, rubbing pieces, hoops for casks, and many other important works. Supplies of good quality growing scarce.

ELM, WYCH OR SCOTCH (*Ulmus montana*, Smith).—Lighter-brown in colour, softer and more straight-grained and therefore more easily split than English elm. Used largely in chair-making, boat-building, and for agricultural implements.

ENG or IN (*Dipterocarpus tuberculatus*, Roxb.).—Weight, 54 lbs. Burma. This dark reddish-brown wood is one of the valuable timbers of Burma. Very durable and in great demand for house and boat-building. Has been used in this country very successfully for parquet flooring; excellent for all constructional work.

(*Gmelina arborea*, Roxb.).—Weight, 36 lbs. India, Burma. Golden-yellow to greyish-white, with a glossy sheen; soft, even-grained, durable; does not warp or crack, easily worked. Used for furniture, door-panels, carriage-building, boats, light planking, etc., and in all works where shrinkage is to be avoided. Roxburgh, writing considerably over a century ago, spoke of the great value of this wood. Will probably be most appreciated for cabinet work.

GREENHEART, DEMERARA AND SURINAM (*Nectandra rodioei*, Schomb.).—Weight, 70 lbs. British and Dutch Guiana and tropical South America. Dark greenish-brown, clean and straight in the grain, hard and heavy; tough, strong and elastic. Heartwood extremely durable. Resists teredo and therefore largely used for piles, wharves and jetties; also in shipbuilding, machinery and planking; one of the best woods for fishing rods. In strength exceeds most other woods, whether tried by transverse or tensile strain. When tested for crushing force in the direction of the fibres it bears the addition of weight after weight till the crushing force is obtained. It then, with a loud report, gives way suddenly and nothing is left but a loose mass of shapeless fibres.

GREENHEART, BURMA (*Heterophragma adenophyllum*, Seem.).—Weight, 48 lbs. India, Burma, Andaman Islands. Bronze to greenish-yellow, greatly resembling the Surinam. Does not warp or split. Suitable for cabinet work.

GUM, BLUE (*Eucalyptus Globulus*, Labill.).—Weight, 50 lbs. Australia. Light-brown, hard, heavy, tough, elastic; somewhat interlocked grain, durable. Used for shipbuilding, telegraph poles, felloes, shafts, spokes and piles. Employed for the piles in Dover Harbour.

GUM, RED (*E. caloplylla*, R.Br.).—Weight, 60 lbs. Australia. Yellowish-red, fairly dense

and hard, splits readily; the prevalence of gum veins impairs its suitability for constructional work. Not durable underground. Used for axe and other handles, spokes, naves, fencing rails, and agricultural implements.

GURJUN (*Dipterocarpus turbinatus*, Gaert.).—Weight, 50 lbs. Andaman Islands and Burma. Reddish-brown, capable of a smooth finish, durable; possessed of an agreeable aromatic scent which is fairly persistent. Has a close, hard, non-fibrous grain which makes the wood very suitable for a number of purposes where smoothness of surface and hard wear are required. Long lengths and large sizes can be obtained free from all defects, and the supply is expected to be on a very extensive scale. The wood seasons slowly, but although unreliable if unseasoned, when properly dried stands well. Where used for joinery work, cabinet work, ships' fittings, and floorings should always be artificially seasoned. Should be quarter sawn where employed in works of importance. Suitable for all the above named purposes and particularly for floorings, solid and parquet, especially where hard wear is required.

HALDU, INDIAN (*Adina cordifolia*, Hook. f.).—Weight, 42 lbs. India, Burma. Lustrous golden-yellow, even-grained, capable of a fine finish from the tool; durable, seasons well. A beautiful wood for cabinet-making and turnery, and is especially suitable for carving.

HICKORY (*Hicoria alba*, Britt., etc.).—Weight, 50 lbs. North America. Brownish-white to reddish-brown, hard, strong, exceedingly tough, springy and elastic; smooth and straight-grained. Liable to shrink and warp, not durable if exposed. Used very largely for spokes and rims of carriage wheels; also for gunstocks, chair-making, and carriage-building; the best wood yet discovered for golf shafts.

HINOKI (*Cupressus obtusa*, Koch.).—Japan. Yellow to rose-red, sweet-scented, fine-grained, takes a high polish. Used in Japan for decorative work in buildings, etc.

HORNBEAM (*Carpinus betulus*, Linn.).—Weight, 50 lbs. Europe. Yellowish-white; hard, heavy, close-grained; loses much weight in drying, tough and difficult to split. Durable if kept dry, but decays quickly if exposed to wet. Used for cogs, handles, mallets and pianoforte keys.

IROKO (*Chlorophora excelsa*, Benth. and Hook. f.).—Often miscalled African teak. Weight, 40 lbs. Tropical Africa. Yellow to brown, darkening on exposure; strong, straight-grained, very durable. Used as a substitute for teak for gun carriages, joinery and cabinet work, building and constructional work.

IRONBARK (*Eucalyptus leucoxylon*, F. v. M.).—New South Wales. Deep red, hard, heavy, strong, difficult to work. Suitable for piers, wharves, etc., and constructional work generally.

JARRAH (*E. marginata*, Sm.).—Weight, 60 lbs. Western Australia. Reddish in colour, hard, dense, straight-grained, with somewhat interlocked fibres; very durable both in and above ground, and almost non-inflammable. An excellent timber, obtainable in very long lengths and wide widths. Used for all heavy constructional and engineering works, piles for docks, wharves, jetties, and fencing. Excellent for flooring, house-building and for street paving blocks; suitable also for cabinet work.

JARUL (*Lagerstroemia Flos-reginae*, Retz.).—Weight, 43 lbs. India, Burma. Light red and lustrous. Used for shipbuilding, constructional work, and for carts; suitable for cabinet making.

KAKI (*Diospyros Kaki*, Linn. f.).—Japan. Dark grey streaked with black. This is the Japanese ebony. Used in turnery and ornamental work.

KARRI (*Eucalyptus diversicolor*, F. v. M.).—Weight, 63 lbs. Western Australia. Greatly resembles jarrah in appearance; red, dense, tough, elastic; produces timber of exceptional size. Suitable for most of the uses to which jarrah is put, though it is not so durable for underground work or in damp situations. Somewhat prone to dry rot; almost non-inflammable. The heart-wood core should be avoided. When 'Powellised,' is now reported as exceedingly durable and termite-proof for sleepers, etc.

KAURI PINE or COWDIE PINE (*Agathis australis*, Salisb.).—Weight, 38 lbs. New Zealand. Yellowish-white or straw colour, strong, fine, and even-grained; planes well and takes a good polish with a silky lustre on the surface; shrinks very little and is remarkably free from defects. Very valuable for deck planking and for fitments in ships; also used for joiners' work and ornamental purposes.

KEYAKI (*Zelkowa acuminata*, Planch.).—Japan. Hard and strong; lustrous and often highly-figured, when it is used for fine cabinet work. Also employed in building and naval architecture; excellent for carving.

KINGWOOD.—Brazil. A handsome dark brown streaked with crimson to violet and purple, fine grained. Used in fancy cabinet work and turnery, generally in the form of veneer.

LABURNUM (*Cytisus laburnum*, Linn.).—Europe. Dark brown to bronze, hard and close grained; takes a good polish. Used in turnery and for pulleys and blocks.

LANCEWOOD (*Guatteria virgata*, Dun.).—Weight, 50 lbs. Central and South America. Light yellow, hard and close grained, elastic. Used for carts, carriages, and shafts, and also for fishing rods.

LANCEWOOD, BURMA (*Homalium tomentosum*, Benth.).—Weight, 59 lbs. India and Burma. Greyish-brown, fine, close and even grained. Takes a very smooth surface, is apt to split in seasoning, durable. Suitable for furniture.

LANCEWOOD, INDIAN GREY (*Vitex glabrata*, Br.).—Weight, 42 lbs. India, Ceylon. Light greyish-brown with a lustrous sheen and a ripple-like figure. Takes a good polish and would be excellent for furniture.

LAUAN (*Dipterocarpus thurifer*, Blanco).—The Philippine Islands. Dark brown, strong and heavy. Suitable for shipbuilding and furniture.

LAUREL-WOOD. See Walnut, Indian.

LEZA-WOOD (*Lagerstroemia tomentosa*, Presl.).—Weight, 50 lbs. Burma. Grey to greyish-brown, soft, works easily and takes a good polish. Would be suitable for furniture.

LIGNUM-VITAE (*Guaiacum officinale*, Linn.).—Weight, 70 lbs. Central and tropical South America. Dark greenish-brown to black, hard, heavy, strong and close-grained; almost imperishable; liable to cup-shake. Used for pestles, mortars, croquet, and other mallets, and for a great variety of purposes. Has a unique value for propeller shafts for steamers on account of its lubricating qualities.

LIGNUM-VITAE, INDIAN (*Berrya ammonilla*, Roxb.).—Weight, 62 lbs. India. Brown to purplish-red, flecked as in English beech; firm, hard texture, and satiny lustre; has a sticky feeling to the touch, planes well. Suitable for decorative cabinet work and turnery.

LIME (*Tilia cordata*, Miller.).—Weight, 30 lbs. Europe. Pale yellowish-white, soft and light; easily cut and carved; not very durable when exposed to the weather. Excellent for carving, for pianofortes and models of buildings.

LUMBAYAO (*Tarrietia javanica*, Bl.).—Weight, 44 lbs. The Philippines. Dark to light red, light and easy to work. Used for furniture.

MAGNOLIA (*Magnolia acuminata*, Linn.).—Weight, 30 lbs. United States. White, soft, not strong, but very durable. Used for interior fittings and occasionally in cabinet work. Somewhat similar to canary whitewood.

MAHOGANY.—Species uncertain. Supplies received from St. Domingo (Spanish), Cuba, Honduras, Mexico, Panama, Nicaragua, Colombia and the districts of Central America generally; the West Coast of Africa. One of the most valuable of all decorative woods, the merits of which are so universally acknowledged that further description is unnecessary.

MAHWA (*Bassia latifolia*, Roxb.).—Weight, 62 lbs. India, Burma. Reddish brown; used for house-building, furniture, naves of wheels, etc.

MALLET-WOOD, INDIAN (*Schleichera trijuga*, Willd.).—Weight, 68 lbs. India and Burma. Light reddish-brown, seasons well, takes a good polish; strong and durable but somewhat difficult to work. Suitable for handles, agricultural implements, and for furniture.

MAPLE (*Acer saccharinum*, Wang.).—Weight, 40 lbs. Canada and the United States. Creamy to yellowish-white; has a fine, smooth surface and a dense, even grain; tough and strong. Excellent for flooring, especially for hard wear, and for veneering and interior finish; also for furniture. Birds-eye maple is the figured variety, and is appreciated for cabinet work.

MARBLE-WOOD, ANDAMAN (*Diospyros Kurzii*, Hiern.).—Weight, 61 lbs. Andaman Islands. A unique and handsome wood, grey streaked with black, smooth and cold to the touch; liable to shrink and warp unless thoroughly seasoned. Valuable for cabinet work and for walking-sticks, etc.

(*Melia composita*, Willd.).—Weight, 28 lbs. India. Pale brown, resembling cedar in this, as also in grain and texture; durable and light in weight. Suitable for sugar boxes, and for boat and yacht building.

(*Mesua ferrea*, Linn.).—Weight, 72 lbs. India, Burma. Dark red, extremely hard, strong and heavy; good sizes procurable. Suitable for sleepers, wood-paving blocks, etc.

MINGRIS (*Koompassia Beccariana*, Taub.).—Borneo. Light red, very hard and heavy; not durable.

MIRABOW or MIRABOO (*Intsia Bakeri*, Prain.).—Weight, 54 lbs. Borneo. Malay States. Reddish-brown, darkening with age, hard, fine, even-grained; often beautifully figured. Tough, durable, and susceptible of a fine polish. Suitable for decorative furniture.

MORA (*Mora excelsa*, Baill. and Benth.).—Weight, 60 lbs. British and Dutch Guiana. Chestnut-brown, hard, heavy, tough. Usually straight in the grain, but sometimes wavy, which gives a beautiful figure. Takes a good polish, and therefore suitable for furniture. Extremely durable; useful for sleepers, and for beams, keelsons, etc., in shipbuilding; and also in a general way in large scantlings for civil and naval architecture.

MULBERRY, YELLOW (*Morus laevigata*, Wall.).—Weight, 45 lbs. India, Burma. Very beautiful golden to chrome yellow, shining and lustrous; has a pretty silver grain; hard and close grained. Suitable for furniture, turnery, and decorative work generally.

MYALL or VIOLET-WOOD (*Acacia pendula*, A. Cunn.).—Weight, 76 lbs. Australia. Rich dark brown, hard, heavy, close grained, often figured. Has a faint scent of violets. Suitable for veneer, turnery, etc.

NIRI (*Xylocarpus borneensis*, Becc.).—Borneo and the Philippines. Dark red, hard and heavy; fine grained and durable, shrinks little in seasoning. Useful for furniture.

OAK (*Quercus pedunculata*, Ehrh., and *Q. sessiliflora*, Sm., etc.).—Europe etc.

British.—Weight 53 lbs. Light-brown in colour, hard, tough, very strong. Does not easily splinter; durable under water, above ground and in alternate wet and dry. Apt to warp and split in seasoning, but when once thoroughly seasoned few woods stand better. Must not be used in immediate contact with iron. Uses so extensive that it would be impossible to enumerate. Should be more extensively used, however, for panelling and decorative work generally, in place of other supplies which are not so good.

Austrian.—So-called Austrian oak was largely used before the war for decorative panelling, floorings, etc., although in point of fact it was more often specified than supplied. A clean, mild oak, generally free from much defect.

Dantzig.—Similar to the above, though slightly stronger and harder; possesses elasticity in a marked degree.

Riga, Libau, and *Odessa* oak are similar to Austrian. The last-named yields slightly larger dimensions.

French.—Resembles supplies of British, but is generally milder in character.

Italian.—Heavier and less elastic than the British; harder and more difficult to work. No supplies have been forthcoming of late years.

American (*Quercus alba, etc.*).—Weight, 42 lbs. Supplies of American oak include the produce of over twenty-two different botanical species, consequently supplies vary largely in quality, texture, durability and colour. American oak is not employed in the best descriptions of work.

Japanese (*Quercus grossesserrata,* Bl., *Q. crispula, etc.*).—Weight, 40 lbs. Similar in appearance to the European, generally closer in texture; slightly milder than the Austrian, from which it is almost impossible to distinguish it except by examination with the lens. Possesses a very uniform colour. Suitable for the best descriptions of work.

Wainscot.—A term used to describe the produce of any oak when hewn, sawn, or reft on the quarter.

PADAUK, ANDAMAN (*Pterocarpus dalbergioides,* Roxb.).—Weight, 48 lbs. Andaman Islands. A handsome crimson-coloured wood, sometimes streaked with black or brown, often finely figured. Seasons and works well, takes a good polish; shrinks very little, does not crack or split; not subject to dry rot. Excellent for all interior decoration and fittings and for furniture. One of the best woods for gun-carriages and ordnance work; has given good results for flooring. Used in America for such work as the trimming of Pullman cars, the decoration of public and private buildings and for furniture.

PADAUK, BURMA (*P. macrocarpus,* Kurz.).—Weight, 60 lbs. Burma. Resembles the Andaman variety, but is darker in colour, harder and heavier. Used for the same purposes, though possibly a slightly inferior wood.

PARTRIDGE WOOD (*Andira inermis,* Kunth.).—Brazil. Reddish-brown to black, figured and mottled. Used for cabinet work, turnery, umbrella and walking-sticks, etc.

PEAR TREE (*Pyrus communis,* Linn.).—Weight, 50 lbs. Europe. Pale brown, tough and difficult to split; close grained. Cuts with great facility in any direction without splitting, and therefore used largely for carving and wood-engraving; also for musical instruments and for turnery. Needs careful and thorough seasoning.

PLANE (*Platanus occidentalis,* Linn.).—Weight, 30 lbs. North America. Sometimes known as button-wood. Light brownish-yellow, shows a fine figure when cut on the quarter. Used for blocks, screws, etc.

POON (*Calophyllum tomentosum,* Wight.).—Weight, 40 lbs. India. Pale, rather reddish mahogany colour with darker red veins. Close, firm, hard grain; takes a smooth surface, stands well. Suitable for decorative cabinet work.

POPLAR (*Populus alba,* Linn., and *P. nigra,* Linn.).—Weight, 30 lbs. Europe. Light reddish-brown, soft, light; neither strong nor durable. Used for such work as turnery, clog-making, and toys; latterly in much demand for plywood.

PRIMA VERA or WHITE MAHOGANY.—North America. Light creamy yellow, often figured. Used for interior decoration.

PURIRI (*Vitex littoralis,* A. Cunn.).—Weight, 60 lbs. New Zealand. Dark brown, hard, heavy, close grained; very strong and durable. Suitable for heavy constructional work such as piles, posts and sleepers.

PURPLEHEART (*Peltogyne paniculata,* Benth.).—Weight, 50 lbs. Tropical South America. Rich purple, hard, heavy, and lustrous; works well. Used for flooring and all ornamental work such as marquetry and turnery.

PYINMA (*Lagerstroemia hypoleuca,* Kurz.).—Weight, 40 lbs. Andaman Islands. Red, hard, seasons well, durable; easy to work. Suitable for house-building, and for spokes and felloes of wheels.

PYINKADO (*Xylia dolabriformis,* Benth.).—Weight, 60 lbs. India. Rich, warm reddish-brown; close, firm, hard, rather cross-grained texture; cold and sticky to the touch. Very heavy, and becomes harder with age. Extremely durable, probably on account of the resinous substances contained in it. Largely used for railway sleepers. Suitable also for paving blocks, telegraph posts, building, piles, and beams of bridges and similar constructional work.

RASPBERRY-JAM WOOD (*Acacia acuminata,* Benth.).—Weight, 60 lbs. Australia. Dark reddish-brown to purple, streaked with black; has a scent like crushed raspberries; somewhat difficult to work. Used in ornamental cabinet work and turnery.

ROSEWOOD, BAHIA AND RIO (*Dalbergia nigra,* Fr. Allem.).—Weight, 60 lbs. Brazil. The first-named is the superior wood. Dark reddish or purplish-brown, streaked with black; faint scent like rosewater. Dense and heavy, takes a fine polish; liable to heart-shake. Used both solid and in veneer for ornamental cabinet work. Less used now than formerly.

ROSEWOOD, INDIAN (*Dalbergia latifolia,* Roxb.).—Weight, 50 lbs. India. Alternatively known as East Indian or Bombay rosewood and Bombay blackwood. Dark purple streaked with black, hard and close grained; takes a good polish. Available in long lengths and very large sizes of perfect quality. Useful for cabinet work; would be excellent for panelling.

SABICU (*Lysiloma Sabicu,* Benth.).—Weight, 50 lbs. The West Indies. Dark brown, sometimes streaked with black, often finely figured; hard, heavy, close grained; susceptible of a good polish. Used for shipbuilding, interior fittings, cabinet work, furniture, etc.

SAL (*Shorea robusta*, Wall.).—Weight, 60 lbs. Burma. Similar in colour to Indian sal, but more even grained; hard and durable. Used for building and also for small work such as tool handles.

SALMON WOOD, INDIAN (*Eriolaena Candollei*, Wall.).—Weight, 51 lbs. Burma. Bright salmon-red, handsomely marked; hard, shining, close grained, takes a fine polish, seasons well. Suitable for decorative cabinet work, bandings, and inlay.

SANDERS, RED (*Pterocarpus santalinus*, Linn. f.).—Weight, 75 lbs. India. Dark claret-red, sometimes nearly black, streaked with dark violet. Valuable for decorative cabinet work and inlay.

SATINEE (*Ferolia guianensis*, Aubl.).—Weight, 55 lbs. South America. Light reddish-brown, hard, tough, elastic; takes a good polish. Suitable for furniture, also for fishing rods.

SATIN WALNUT (*Liquidambar styraciflua*, Linn.).—Weight, 40 lbs. North America. Should be called gum, by which name it is known in America; has been called hazel pine, sweet gum, and Californian red gum in England. Has no qualities which justify its being called either walnut or pine. Pale reddish-brown, soft, close grained, has a smooth, satiny sheen. Warps and twists badly in drying, and even when seasoned is susceptible to change in the atmosphere. Used for cheap furniture; quite unfitted for street-paving, for which purpose it was tried in London some years ago.

SATINWOOD, WEST INDIAN (*Zanthoxylum*, sp.).—Porto Rico, St. Domingo and the West Indies generally. Chrome yellow to golden, maturing with age to a rose yellow; has a beautiful satiny lustre, often finely figured. Used for the finest cabinet work, brush backs, etc.

SATINWOOD, EAST INDIAN (*Chloroxylon Swietenia*, DC.).—Weight, 60 lbs. Ceylon and occasionally from India. Uses similar to the above.

SISSOO (*Dalbergia Sissoo*, Roxb.).—Weight, 50 lbs. India. Rich warm brown, sometimes streaked with golden or darker brown. Firm, hard, even texture; takes a very smooth surface and a good polish; strong and durable, seasons well. Capable of being carved to any depth in the most intricate shapes without splintering. Suitable for furniture and carving, also for gun-carriage wheels.

STRINGYBARK (*Eucalyptus obliqua*, L'Hérit.).—Weight, 60 lbs. Australia and Tasmania. Brown, hard, heavy, strong, tough and close grained. Splits easily; requires careful seasoning; liable to shakes and gum veins. Useful for a large variety of purposes, including fencing, flooring, piling, paving, mine timbering, and shipbuilding.

SYCAMORE (*Acer Pseudo-platanus*, Linn.).—Weight, 40 lbs. Europe. Yellowish-white, often finely-figured, even grained, lustrous, easily worked; apt to crack and warp during seasoning. Used for rollers for calico printing, also for washing machines, and, in the form of veneer, for panelling in carriages and railway coaches. When stained grey forms the 'greywood' of commerce.

TALLOW-WOOD (*Eucalyptus microcorys*, F. v. M.).—Weight, 60 lbs. Australia. Yellowish-brown, sometimes wavy in grain, strong and durable; liable to shakes. Used for wheelwrights' work, piling, and flooring.

TALLOW-WOOD, INDIAN (*Terminalia Chebula*, Retz.).—Weight, 48 lbs. India. Purplish-grey to brown, with a fine ripple marking. Fairly durable, takes a good polish; cross grained and hard, somewhat difficult to work. Suitable for furniture, house-building, and golf heads.

TAPANG (*Koompassia excelsa*, Taub.).—Borneo. Dark reddish-brown, dense and heavy; durable and strong, but very brittle; obtainable in large sizes. Suitable for heavy constructional work.

TEAK, BORNEO.—This term is an entire misnomer, having been wrongfully applied to a Borneo wood which is certainly not teak; *Tectona grandis* has never been found in Borneo.

TEAK, JAVA (*Tectona grandis*, Linn. f.).—Weight, 43 lbs. Java. Shorter in length and inferior in quality to Indian teak; otherwise similar.

TEAK, MOULMEIN, RANGOON, and BANGKOK (*Tectona grandis*, Linn. f.).—Weight, 45 lbs. India, Burma and Siam. Yellow to brown, darkening with age; moderately hard and strong. Contains an essential oil which acts as a preservative; extremely durable; often unsound at the centre. The chief export timber of India and Burma. Used for an immense variety of purposes; for the backing of armour plates in battleships, also house and boatbuilding and all constructional work; flooring, sleepers, carpentry, carriage-building, etc.

THINGAN (*Hopea odorata*, Roxb.).—Weight, 40 lbs. India. Bright canary yellow, resembling satinwood; mild, straight grain similar to mahogany and of the same texture; very durable. large supplies available in good sizes. Excellent for cabinet work, etc.

THITKA (*Pentace burmanica*, Kurz.).—Weight, 44 lbs. India. Light red, resembling cedar, with a pretty silver grain. Strong and durable; takes a very smooth surface and a fine polish. Suitable for artistic decorative work.

TOTARA (*Podocarpus Totara*, A. Cunn.).—Weight, 30 lbs. New Zealand. Red, fine, and even-grained, hard, heavy, tough, and very durable. Does not warp or twist; resists teredo. Used for piles, sleepers, telegraph poles and general building purposes; suitable also for interior fittings, etc.

TUART (*Eucalyptus gomphocephala*, DC.).—Weight, 70 lbs. Australia. Creamy-yellow, hard, very heavy, tough, durable; has an interlocked grain. One of the strongest timbers known and in demand where special strength and hardness are necessary. Used for railway wagons, engine-bearers, ships' beams, planking, shafts, naves and felloes, and wheelwrights' work generally.

TULIP-WOOD (*Physocalymma scaberrimum*, Pohl.).—Brazil. Striped pink to rose colour. Used chiefly for bandings, inlay, and marquetry.

TULIP-WOOD, INDIAN (*Dalbergia Oliveri*, Gamble).—Weight, 66 lbs. India. Striped pinkish-red; very hard and cross-grained. Suitable for similar purposes to the above.

TUPELO (*Nyssa sylvatica*, Marsh.).—Weight, 40 lbs. North America. Also called tupelo gum. White to light yellow, paling somewhat on exposure to air; smooth and close-grained; liable to warp. Used in a general way as a substitute for whitewood, also for electric casings and for furniture.

VENGAI (*Pterocarpus marsupium*, Roxb.).—Weight, 55 lbs. India. Golden yellowish-brown with lighter and darker streaks; smooth and lustrous; firm and hard with contrary grain; has a good figure when cut on the quarter. Used for cabinet work and interior fittings.

WALNUT (*Juglans regia*, Linn.).—Weight, 40 lbs. Europe and Asia. Greyish-brown, often finely marked and figured; hard, firm, close-grained; takes a good polish. Liable to the attacks of worm (beetle) when used for furniture. The finest wood for gun-stocks, as it withstands shock and does not warp. Used for pianofortes and furniture generally.

WALNUT, BLACK (*Juglans nigra*, Linn.).—Weight, 40 lbs. North America. Chocolate-brown to grey, darkening with age. Easily worked and more durable than European walnut; also less liable to insect attack.

WALNUT, INDIAN (*Albizzia Lebbek*, Benth., and *A. procera*, Benth., *A. odoratissima*, Benth.).—Weight, 46 lbs. India. Rich warm brown, streaked with yellow and black; often has wavy marks and broken roe and mottle. Firm, hard texture; takes a good surface from the tool and has a bright lustre; seasons and stands well; available in large sizes. Suitable for furniture, panelling, veneer, turnery, and all decorative work.

WALNUT, INDIAN BLACK (*Terminalia tomentosa*, W. and A.).—Weight, 55 lbs. India. Dark brown, variegated with darker streaks; needs careful seasoning; large supplies available. Suitable for decorative, cabinet, and instrument work.

WANDOO (*Eucalyptus redunca*, Schau.).—Weight, 70 lbs. Australia. Brownish-red, very hard, strong, dense and durable. Equal to jarrah for railway sleepers; also used for piles, bridge-building, wheelwrights' work, boat-building, fencing, and general building work.

WHITEWOOD, CANARY (*Liriodendron tulipifera*, Linn.).—Weight, 30 lbs. North America. Called in America, poplar, yellow poplar, tulip tree, etc.; known in England as whitewood, canary whitewood, and canary wood; in Scotland, wrongly called basswood. Pale yellow, soft, light, tough; easily worked, takes a good polish and stains well; liable to shrink and warp. Useful for indoor building, joinery, wainscoting, chairmaking, carriage-building, etc.

WILLOW (*Salix alba*, Linn., and *S. coerulea*, Linn.).—Weight, 30 lbs. Europe. White, light, soft, smooth-grained; very durable in water. Used for brake blocks on railway wagons, as it does not readily fire with friction. Largely employed for the making of artificial limbs and for cricket bats.

YACAL (*Shorea*, sp.).—The Philippines, Borneo. Brown, darkening on exposure; good and durable. Used for railroad ties and for constructional work generally.

YANG (*Dipterocarpus*, sp.).—Siam. Similar in all respects to the Eng of Burma (*q.v.*).

YELLOW HEART (*Fagraea fragrans*, Roxb.).—Weight, 60 lbs. Burma. Light yellowish-brown, hard, close-grained, very durable. Used in Burma for house-building, piles and joinery, but in this country, where supplies are now arriving, it will probably be most appreciated as a first-class cabinet-wood.

YELLOW JACK-WOOD (*Artocarpus integrifolia*, Linn. f.).—Weight, 40 lbs. India, Burma. Rich gamboge yellow, darkening somewhat on exposure; has a hard and soft contrary grain. Used for decorative furniture work, brush backs, etc.

YEW (*Taxus baccata*, Linn.).—Weight, 50 lbs. Europe, India, etc. Reddish-brown to amber, often finely figured; very hard, close-grained and heavy. Said to be more durable than other European wood. Tough and elastic. Used for chair-making, walking sticks, furniture; and in the form of veneer for decorative work generally; also for axles, cogs for mill-wheels, etc.

ZEBRA WOOD, RED (*Melanorrhœa usitata*, Wall.).—Weight, 56 lbs. India. Red, with darker red or golden streaks; very hard. Useful for tool handles, and general decorative work. Has been recommended for building, sleepers, gun-stocks, etc.

Durability of Timber.

WOODS WHICH RESIST THE SEA-WORM (*Teredo navalis*).—No complete list of such timbers is possible, for reports vary as to this quality being possessed by any particular timber, while the increase of scientific research and the resultant preventive measures might cause such a list to be considerably enlarged. It is therefore recommended to institute enquiries concerning the timber at the time of purchase.

This same principle should be applied when considering the durability of timber in other particular circumstances.

Strength of Australian Timber.

The following table, compiled by Professor Warren, of the Sydney University, sets forth the respective value of all the Australian best hardwoods in comparison with the Western Australian Jarrah, Karri, and Red Gum :—

Timber.	Weight per Cubic Foot.	Average Strength in Lbs. per Square Inch.			
		Transverse Strength. Modulus of Rupture. 54 ins. × 6 ins. × 4 ins.	Tensile Strength.	Compressive Strength 12 ins. × 3 ins. × 3 ins.	Shearing Strength 6 ins. × 6 ins. × 3 ins.
N.S.W. Timbers :	Lbs.				
Ironbark	75·18	18,204	17,900	10,500	2,200
Tallow-wood	77·06	15,300	13,400	8,500	1,660
Blackbutt	66·69	14,800	21,000	8,600	1,700
Blue gum	73·64	14,700	15,900	7,800	1,800
Grey gum	67·32	17,600	22,000	9,500	2,100
Spotted gum	62·19	15,300	16,400	8,500	2,200
Turpentine	69·34	14,400	17,800	8,500	1,600
Grey or white box	73·62	15,950	21,564	8,021	2,110
Murray red gum	62·19	11,267	13,618	9,397	2,039
Stringybark	71·33	13,083	15,976	6,098	2,089
W.A. Timbers :					
Jarrah	62·0	12,040	16,047	6,839	1,878
Karri	—	11,208	13,920	7,132	1,637
Red Gum	62·5	10,739	22,725	5,476	1,556

Content Sizes and Weights of Timber.

40 cubic feet of unhewn timber
50 " squared "
600 super. feet of 1-inch planks or deals
400 " 1½ " "
300 " 2 " "

240 super. feet of 2½-inch planks or deals
200 " 3 " "
170 " 3½ " "
150 " 4 " "
} = 1 load.

120 deals = 1 hundred. Battens are not over 7 inches wide. Deals are not over 9 inches wide. Planks are mostly 11 inches wide.

One square (100 *feet superficial*) *of flooring requires :—*

12-feet deal boards :—	Number.
Rough	12¼
Edges shot	12½
Wrought and laid folding	13
Wrought and laid straight joint	13½
Wrought, ploughed, and tongued	14

12-feet battens :—	Number
Rough	16
Edges shot	16½
Wrought and laid folding	17
Wrought and laid straight joint	18

Number of cubic feet in one 1 of timber : Ash, 45 ; elm, 60 ; mahogany, 34 ; beech, 51 ; fir, 65 ; oak, 39.

Standards by which Deals are Sold.

Planks, deals, and battens are usually sold by the number required to make up the same cubic content as 6 score or a long hundred of some standard size ; thus, in London the Petrograd standard is used, which with others is given below :—

Standard.	No. of Pieces.	Size.	Feet Cube.	Feet Superficial.
Petrograd	120	12 ft. × 11 ins. × 1½ ins.	= 165	= 1,320
London and Dublin	120	12 ft. × 9 ins. × 3 ins.	= 270	= 1,080
Christiana hundred	120	11 ft. × 9 ins. × 1½ ins.	= 103⅛	= 990
" "	60	15 ft. × 11 ins. × 1½ ins.	= 103⅛	= 825
Quebec short hundred	100	12 ft. × 11 ins. × 2½ ins.	= 229⅙	= 1,100
" long "	120	10 ft. × 11 ins. × 3 ins.	= 275	= 1,000
Drammen	120	9 ft. × 6½ ins. × 2½ ins.	= 121⅝	= 585

Prepared floorboards are sold by the customary square, a given number of feet run, as below varying with the width, so as to approximate to the square of 100 feet superficial :—140 feet run of 9-inch boards, 160 feet of 8-inch, 170 feet of 7½-inch, 180 feet of 7-inch, 185 feet of 6¾-inch 200 feet of 6-inch, 210 feet of 5⅝-inch, 220 feet of 5½-inch, 230 feet of 5¼-inch, 240 feet of 5-inch.

To cut the Best Beam from a Log.

Divide the diameter, *ab* (fig. 668), into three equal parts, *af*, *fe*, *eb*, and from *e* and *f* draw the lines *ed*, *fc*, at right angles to *ab* ; join *ac*, *ad*, *bc*, and *bd* ; then *acbd* is the cross-section of the beam required.

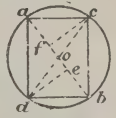

FIG. 668.

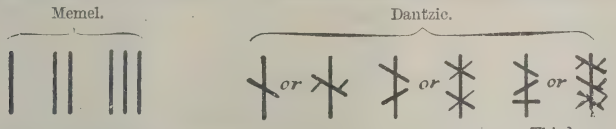
To cut the Stiffest Beam from a Log.



The stiffest cross-section will be that in which the diameter is divided into four equal parts and perpendiculars drawn as above described.

Selection of Timber.

In selecting timber the most convenient sizes are 12 inches square. Choose the highest in colour, where the strong red grain appears to rise to the surface; avoid spongy hearts, porous grain, and dead knots.

SCRIBE MARKS.

The following are the 'scribe marks' indicating the quality of Memel and Dantzic timber :—

Memel timber is generally about 13½ or 14 inches square ; Dantzic timber about 18 or 19 inches. When the *slab deals*, or outsides, have been cut away, the log that remains of this timber is generally 14 to 15 inches square.

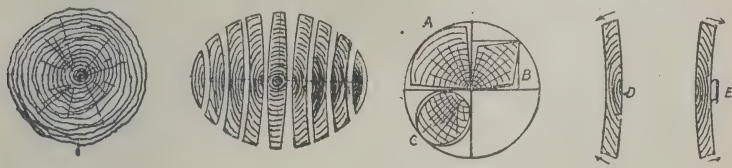


FIG. 668A.

SHRINKAGE OF TIMBER.

A. Sector becomes narrower. B. Square becomes rhomboidal. C. Circle becomes elliptical.

The outside layers contract most, these being youngest. The centre plank will therefore contract at edges, the side planks contracting as at D. If a good shaving is taken off, even thoroughly dried wood will shrink, as in E, the new surface exposed shrinking and drawing the wood inwards.—*Horobin.*

Seasoning Timber.

Timber is improved and rendered less liable to warp by being immersed in water some weeks If long immersed, when exposed to the air it becomes brashy and useless. Seasoned timber should be piled under shelter and kept dry, and should have a free and gentle circulation of air ; bottom layer to be placed on timbers 24 ins. from the ground, and each subsequent layer to have an inch space between.

TIME REQUIRED FOR SEASONING TIMBER.

Oak.—From 4 to 8 square inches, about 6 months; under 12 square inches, 10 months; under 16 square inches, 14 months; under 20 square inches, 18 months; under 24 square inches, 22 months; above 24 square inches, 26 months.

Fir.—Half the foregoing time in each case.

Artificial Seasoning of Timber.

(Contributed by G. Stanley Walpole, D.Sc., F.I.C.)

Artificially seasoned timber, when the seasoning is scientifically carried out, is as good, and, in some cases, better than similar timber which has been seasoned by natural means.

The following show the results of actual tests carried out by a Government Department :—

Nature of Timber.	Natural Seasoning.		Artificial Seasoning.	
	Breaking Load. lbs./sq. ins.	Elastic Limit. lbs./sq. ins.	Breaking Load. lbs./sq. ins.	Elastic Limit. lbs./sq. ins.
American Walnut . .	15,300	7,030	15,000	7,000
Mahogany	11,700	6,230	12,700	6,880
English Ash . . .	10,900	5,500	14,000	7,000
Spruce	8,500	4,500	9,000	4,000

Artificial seasoning, properly carried out, reproduces in the kilns or chambers the best atmospheric conditions, and the process is continuous. With natural seasoning the process of drying frequently comes to a standstill and remains so for long periods owing to adverse weather conditions.

All systems of artificial seasoning depend upon the circulation of air around the timber which is stacked in a kiln or chamber in such a manner that practically the whole surface of the timber is exposed to the currents of air. Such air is warmed to the required degree, but in a correctly designed plant the temperature of the air during any period is limited to that figure, determined by experience, which ensures that evaporation of moisture takes place at a 'safe' rate, the term 'safe' being used to indicate that the material is not deteriorated in any way.

Timber dryers can be divided into two classes; the first those in which the material to be dried is moved through zones of air each differing in temperature and humidity from the neighbouring one. The second type is that in which the timber itself remains stationary, the air conditions being varied throughout the period that the timber is in the kiln. The first type are termed 'Progressive or Tunnel Dryers' and the second type 'Compartment Dryers.'

Progressive dryers may be again divided into two sections; first those employing the use of fans to ensure positive air circulation (Sturtevant type), and secondly those which depend for air circulation upon the difference of temperature between one part of the kiln and another (Erith type). In the case of compartment dryers, fans are almost invariably used, as thermal circulation would not be satisfactory for that type.

The selection of the right class of dryer for any particular duty is a matter of considerable importance, and the following remarks may be of service in guiding manufacturers and others in this matter.

In cases where the duty of the proposed seasoning plant is definitely known in advance and where such duty consists of the drying of large quantities of timber (particularly soft woods) of uniform grade and thickness, the progressive type dryer will probably be found the most economical. In cases where it is impossible to predict the exact duty of the plant, or where many different kinds and thicknesses of timber have to be dealt with, the compartment system will prove more satisfactory, as when properly installed it is very 'elastic' in nature. Further, if there is a possibility that the nature of the trade will alter, according to varying conditions, the compartment system would be preferable to the progressive type, by reason of the fact that, should different classes of timber have to be dealt with, the apparatus, as originally installed, would require very little, if any, modification.

PROGRESSIVE DRYERS.

This type of dryer gets its name from the movement of the timber through the tunnel. The timber is piled on trucks which run on suitable rails right through the tunnel from one end to

the other. The tunnel is first completely filled, and afterwards the introduction of a truck of green timber displaces a similar truck of seasoned material at the opposite end. The movement of the trucks is thus said to be 'progressive.' Briefly, the plant itself comprises a long tunnel constructed of brickwork or concrete or, in some cases, of timber. There are doors at both ends and the necessary rail equipment is also provided upon which the trucks run in passing through the dryer. In the case of the 'fan-less' progressive dryers (Erith type) there are a number of steam pipe coils arranged below the running rails. In cases where the rail level of the kiln must be the same as the general ground level, the spaces for the coils must be excavated, but in other cases it may be possible to raise the rail level of the kiln a few feet in order to give the necessary space for the pipes under the tracks.

In the fan-less (Erith) type of progressive dryer the pipe coils are arranged in such a manner that circulation of air is obtained from end to end of the kiln, and the majority of the heating coils are grouped together near the 'dry end' of the plant. The air in passing over the timber absorbs moisture, and the plant is so arranged that the trucks of green timber meet first of all air having a low temperature and a high humidity. As the truck passes through the dryer it meets air having gradually increasing temperature and decreasing humidity.

The other type of progressive dryer (Sturtevant) depends for air circulation upon centrifugal fans, and this means that the air circulation and temperature are under *separate* control. The arrangement of trucks and rails in this type are generally similar to those for the 'fan-less' system, but in this case no excavations for steam coils are necessary, as the heater is fixed entirely outside the dryer in a small room or shed adjoining. For a given output the ground area occupied by the fan type (Sturtevant) progressive dryer is less than the fan-less (Erith) type. As previously indicated, both systems of tunnel or progressive dryers are suitable for large quantities of uniform timber such as floorboards, match boarding, etc. The application of the progressive systems are, however, somewhat limited, and for cases where a more elastic plant is desired it is undoubtedly better to adopt the

Compartment Dryers.

In this system a number of compartments or kilns are built, generally of brick or concrete, and these are loaded with timber either by hand piling or by truck piling. It should be noted, however, that if truck piling is adopted it is only for convenience in handling the material, and is not essential to the working of the dryer as such. The number of compartments may vary from one to (say) six, all being supplied by one central plant. For a larger number of compartments it is generally desirable to divide the same into groups, each dealt with by a separate plant. Speaking generally, it may be said that for a given output the ground area required for the compartment system is less than with the 'fan-less' progressive type. Further, the compartment system is much more easy to arrange in cramped positions, as with the progressive type a considerable *length* of site is necessary to allow of proper working of the system.

With the compartment system, air is introduced through a duct in each compartment along the side wall near the floor, the air passing over and under the piled timber (which is arranged with its length in the direction of the length of the chamber), and then passes out through a corresponding duct on the opposite side of the kiln. The air circulation is made positive by means of centrifugal fans arranged in a small chamber either at one side or on top of the dryer, and in this system means are provided to enable each compartment to be under separate and independent control both as to temperature and humidity. Thus it is quite possible to deal with very different classes of timber in adjacent compartments simultaneously. Further, the stage of drying reached in each of the different compartments may be quite different, and the benefits of this must be at once apparent to those interested.

A very important adjunct of the compartment system is the *Guide Chart System of Control* (Sturtevant patent). This appears to be a scientific solution of the problem, and the object is to reproduce in each kiln, during the whole period of seasoning, ideal conditions previously determined by investigation and experience. The working of the system is briefly as follows: In each compartment, or kiln, a self-recording hygrometer is arranged, this instrument comprising wet and dry bulb thermometers actuating levers terminating in pen points which rest against a revolving drum rotated by clockwork. A guide chart is used for each variety and thickness of timber, and upon this chart are already marked guide lines indicating both the dry bulb and wet bulb temperatures which should be given from day to day in that particular compartment. This chart is wound on a spool and one end attached to the clock drum which, in rotating, gradually draws the chart off the spool on to the drum. The dampers, etc., in connection with each compartment are operated by hand at intervals, so that the conditions in the compartment correspond to those given by the guide lines on the chart. Thus not only do the guide lines give the conditions to be aimed at, but the pen pointers make a permanent record showing how nearly the actual conditions have approached the ideal conditions. It will thus readily be seen that the Guide Chart System acts also as a check on the attention of the kiln operator.

A large number of guide charts have already been prepared by the Sturtevant Engineering Co. Ltd., to suit various classes and thicknesses of timber, both hard and soft, and once the best conditions for a particular grade of timber have been established, similar conditions for subsequent batches can be reproduced as required.

DECREASE IN DIMENSIONS OF TIMBER BY SEASONING.

Wood.	Shrinkage	Wood.	Shrinkage.
	Inches.		Inches.
Canada cedar	14 to 13¼	Southern pitch pine	18⅜ to 18¼
Elm	11 „ 10⅜	Spruce	8½ „ 8⅜
English oak	12 „ 11⅛	American white pine	12 „ 11⅛
Northern pitch pine	10×10 „ 9¼×9¾	Northern yellow pine	18 „ 17⅛

COMPARATIVE WEIGHT OF GREEN AND SEASONED TIMBER.

Wood.	Weight of Cubic Foot in Lbs.		Wood.	Weight of Cubic Foot in Lbs.	
	Green.	Seasoned.		Green.	Seasoned.
Ash	43⅞–63½	32½–59	Oak	58½–63	43–62½*
Beech	56¼–63½	41–52	Riga fir	23¾–63¾	—

(*Nördlinger.*)

* The similarity in the maximum figures for green weight of all four species, and the near approximation to the weight of a cubic foot of water (62½ lbs.) should be noted.

PERCENTAGE OF LOSS OF WEIGHT IN SEASONING.

Red pine	12 to 25	Larch	16 to 25	Elm	About 40
American yellow pine	18 to 27	Oak, British	16 to 30	Mahogany	16 to 25

Preservation of Timber.

In order to keep timber sound it should be kept free from all moisture and be well ventilated. Some timbers, such as oak, beech, elm, and others, will last for a very long time if kept constantly under water; oak piles have been known, under these conditions, to last hundreds of years. Timber exposed to alternate moisture and dryness lasts a very short time.

Slaked lime hastens decay of timber, which should therefore in buildings be protected against contact with mortar.

Timber is destroyed by either wet- or dry-rot. Both wet- and dry-rot are due to different fungoid growths, and in both cases gases, principally carbon-dioxide and hydrogen, are given off. Dry-rot is usually caused by want of ventilation; damp and moderate warmth encourage it. The sap-wood is usually attacked first. It often occurs where ends of beams are built into walls, where wet and unseasoned timber is painted, where a damp floor is covered with oil-cloth or other impervious covering, and in warm cellars. The seeds of the dry-rot fungi are carried about readily, and once it breaks out in one part of a building the timber in other parts may become infected.

Timber is best preserved by being well seasoned, kept dry, and ventilated.

Painting or tarring will preserve timber, provided the latter is thoroughly dry and well seasoned; otherwise it only confines the sap and moisture and causes rot.

Tredgold doubted the utility of painting timber which was not exposed to the weather.

STERNOCARBOL WOOD PRESERVATIVE.

(*Messrs. Sterns Ltd.*)

This preparation, applied externally with an ordinary brush, soaks into the interior of the wood, and is claimed not only to prevent all kinds of internal decay, but to enable the wood to successfully defend itself against external attack.

STORING LOGS.

Logs stored on skidways or left in the woods during the summer months may be damaged in a number of ways, principally through sap-staining, insect attack, decay, and checking.

Storing under water will prevent 'blue stain,' checking, insect attack, and decay, except that logs in sea-water, where marine borers are active, would be subject to attack. Wood of any species completely submerged in water will resist decay indefinitely. Alternate wetting and drying favour decay. Storing on skids in such a way that the air can circulate freely around each log will prevent the accumulation of moisture and thus retard decay. Such storing, however, is liable to increase checking, and, unless the bark is removed, will have little effect in preventing insect attack. The skids should be situated where there is good air circulation, and they should be raised off the ground. Weeds and brush should be cut down. Peeling the bark completely from the logs will do much to eliminate insect attack and retard decay

by removing the protection required by many insects and by allowing the logs to dry more rapidly. It will favour checking, however. Painting the ends of the logs will very materially retard the loss of moisture and thus retard end checking. If the logs are peeled and properly piled on skids, painting should not increase the danger from decay or sap stain. A yellow ochre or barn paint will do fairly well for the purpose. Painting the peeled surfaces with coal-tar creosote will be useful in preventing sap decay, and if applied soon enough may be effective in retarding sap stain. Any grade of creosote in common use for wood preservation is suitable, and expensive oils are unnecessary. (*'Bulletin of the Hydro-Electric Commission of Ontario.'*)

Preservative Processes.

Charring timber.—The ends of posts sunk into the ground are often charred in order to prevent rot, but recent experiments appear to show that the charring is ineffective and useless.

Vulcanising.—The wood is heated in a closed cylinder from 8 to 12 hours under a pressure of 150 to 200 lbs. per square inch and a temperature of from 300° to 500° F.

Drying.—Compressed, superheated and dried air is circulated in order to remove excessive moisture; it is claimed that the sap undergoes a chemical change and solidifies in the pores as an antiseptic matter in cooling.

Sugared timber.—A paper was read before the British Association at their meeting in 1903 on the preservation, seasoning, and strengthening of timber by means of boiling it in a saccharine solution and afterwards evaporating the moisture in a drying chamber. This process filled the interstices of the wood with a substance akin to the wood itself, rendering it more solid, firm and compact. The dried sap of the sugar-cane acted in timber much as mortar did in a stone wall, binding the otherwise loose materials strongly together.

Different methods of preserving timber by impregnation with solutions of metallic salts, such as bichloride of mercury (*Kyanising*), sulphate of copper (*Boucherising*) and chloride of zinc (*Burnetising*), have met with little success.

In the 'Ferrell' process, the principal constituents of the injected solution are sulphate and chloride of aluminium.

Creosoting.

(Contributed by Robert S. Vesey, Member of the Society of Chemical Industry.)

Modern Methods of Creosoting.

Creosoting is recognised as the most efficient method of preserving timber, and all Railway Companies in this country have their sleepers and crossing timbers treated in this way. The process is also generally used for the preservation of telegraph poles, piles, posts, and the like. Softwood sleepers untreated seldom last more than three to four years, whereas their average life when creosoted is about fifteen years, and even then, in most cases, the sleepers are only removed from the track owing to their having become chair-worn, and thereafter the bulk have many years life in them as siding sleepers or fence posts.

The 'Full Cell' Process of creosoting is generally preferred to the 'Empty Cell' or 'Rüping' Process, which latter principally aims at penetration and the withdrawing of two-thirds of the creosote at the end of the operation. Although only about one-third of the creosote used for the 'Full Cell' process is left in the timber in the case of the Rüping Process, the cost of this treatment is nearly two-thirds the cost of the 'Full Cell,' and in this country it has seldom been made use of.

Construction of Creosoting Plants.

Creosoting is carried out in cylinders or retorts 75 to 105 ft. in length by 7 ft. in diameter, the average plant consisting of three, which are erected upon underground covered storage tanks of $\frac{3}{8}$-in. steel, and usually 7 ft. deep, two of these tanks being used in conjunction with each cylinder. The cylinders are of $\frac{7}{8}$-in. steel plate tested to stand at least 400 lbs. pressure per sq. in., and are each fitted at the bottom with two suction pipes for lifting and dropping the creosote to and from the cylinders; at the top of each there is a vacuum valve, pressure valve, overflow pipe, and safety valve. They are fitted with a railway track of about 2 ft. 6 ins. gauge, to take the steel bogies loaded with the timber which is to be creosoted, and 'holding-down' bars are fitted throughout the entire length to prevent the bogies floating while the process is being carried out; each load is either chained or fixed to the bogie by means of arms. Modern plants are fitted with doors at each end of the cylinders to allow the same to be charged or withdrawn from either end, the doors being fixed to the cylinder and swinging on a projecting arm fixed to the top; they can be easily opened and closed by two men. These doors are sealed with about twenty screws 12 ins. long by $2\frac{1}{2}$ ins. diameter, and are tightened by means of a large hand spanner.

The storage tanks cover the whole area occupied by the cylinders, and generally project about 2 ft. to 3 ft. at the sides, and about the same distance at the ends. This additional length at the ends is left open for a space of about 3 sq. ft. and is necessary for allowing the drainage from the cylinders, at the end of the process, to enter the tanks. A portable bridge of rails connects the creosoting cylinders with the bogie roads in the works, and this is of course removed when the cylinder doors are being opened or closed. The cylinders are usually covered with asbestos

to enable the heat of the creosote to be maintained, although in impregnating the timber there is always a reduction in the temperature of the oil; in some cases steam coils are fitted in the cylinders. The storage tanks should always be fitted with coils to enable the creosote to be kept at a temperature of 140° to 150° F., although in America very much higher temperatures are used. These tanks are used for the filling of the cylinders, and to obtain additional creosote for impregnation a smaller underground tank is installed, which is usually built in concrete and is placed in the boiler-house; it is known as the 'Pressing' tank, and on it are fitted the vacuum and pressure pumps.

Working Process.

About 50 cu. ft. of the timber to be creosoted is selected as an average to test the amount of creosote absorbed, and this is weighed before and after creosoting. Immediately the doors have been screwed down, the vacuum pump is started and the air extracted from the cylinder, about 25 ins. of mercury being obtained. This vacuum being maintained, the suction cocks are opened and the cylinder is nearly filled from the two storage tanks immediately underneath; but to complete the filling, the suction cocks are closed, and the pressure pump used for about two minutes to pump in sufficient creosote, the additional oil being taken from the pressing tank. The operator then records from the gauge the number of gallons of oil in the pressing tank, and continues working the pressure pump until the required number of gallons to impregnate the timber have been injected, the amount varying according to the specification. In the case of well-seasoned Baltic Red Fir or Scots Fir, 8 to 10 lbs. per cu. ft. may be injected with 60 to 80 lbs. pressure per sq. in. As soon as sufficient oil has been injected the pressure pump is stopped, the suction valves opened, and the creosote dropped back into the storage tanks. The cylinder doors are then opened and superfluous oil allowed to drain from the timber, and although circumstances will not always permit, no charge should be withdrawn for at least two hours.

Time taken for Carrying out Process.

However well stowed the bogies might be with the timber to be creosoted, the cylinders are only from 50 to 55 per cent. filled, so that a large quantity of creosote is required in connection with each charge. The following is about the average time taken to carry out the creosoting of seasoned Baltic Red Fir with a modern plant:—

Obtaining 25 in. vacuum and lifting oil from storage tanks to cylinder, and completely filling by means of pressure pump—8 to 10 minutes.

Injecting 10 lbs. of cresote per cu. ft. with pressure pump at 60 to 80 lbs. pressure per sq. in. (not maintained, but which is sufficient to inject this quantity of oil)—6 to 10 minutes.

Dropping creosote to storage tanks at end of process—15 minutes.

During recent years the importation of Oregon and Pitch Pine sleepers has considerably increased, which has necessitated the use of higher pressures for creosoting the same, and much longer time being taken to carry out the process. Seasoned Oregon Pine will seldom take more than 2 to 4 lbs. of creosote per cu. ft. at 200 lbs. pressure maintained for 4 hours with the creosote at 150° F., although if sappy pieces are selected it is possible to inject up to 10 lbs. per cu. ft., but these cases are very exceptional in this country. With the various classes of Pitch Pine met with in England ('Longleaf,' 'Shortleaf,' and 'Loblolly') the absorption varies very considerably, and seasoned hard grown 'Longleaf' Pitch Pine will seldom absorb more than an average of 5 lbs. per cu. ft. with a pressure of 200 lbs. per sq. in. maintained for 4 hours. In the case of 'Shortleaf' the absorption would average 8 to 12 lbs. per cu. ft. with the same pressure and time, but 'Loblolly,' which is very sappy and unsuitable for use where strength is required, will absorb up to 20 lbs. of creosote per cu. ft. Seasoned Portuguese Pine will also absorb 10 to 14 lbs. of creosote with low pressure, but this timber is seldom met with in this country. Seasoned Larchwood (Northern Europe and home-grown) will on the average only absorb 5 to 7 lbs. per cu. ft. with high pressure maintained, as in the case of Oregon Pine. Although other species of timber are creosoted in this country, at least 95 per cent. are of Baltic Red Fir, Scots Fir, Oregon, and Pitch Pine, the majority being Baltic Red Fir, which is nearly always preferred for sleepers.

Specification of Creosote Oil.

There has been a good deal of controversy over the question of the best grade of creosote for use in the preservation of timber, some authorities favouring the naphthalene bases, and others placing more importance upon the tar acids. The following is the *average* specification stipulated by those who have creosoting to carry out in this country:—

1. The creosote used, to be obtained from the distillation of coal-tar, free from all impurities, and to be fluid at 75° F.
2. Specific gravity to be between 1·040 and 1·080 (water at 60° F. being 1·000).
3. To yield not more than 75 per cent. upon being distilled to 600° F.
4. Tar acids, not less than 8 per cent.
5. Water, 3 per cent. maximum.
6. In some cases the percentage of naphthalene is not mentioned; in others a minimum of 10 per cent., and a maximum of 30 per cent., and sometimes the specification states that this is to be kept as low as possible. There is no doubt that in the case of piles which are in contact with water they should be creosoted with oil containing a percentage of naphthalene, as this prevents the exudation of the more fluid parts of the creosote, and also assists in preventing the entrance of the water.

British Standard Specification for Creosote.*

Suitable for the treatment of Railway Sleepers and Telegraph, Telephone, and Hangar Poles
(*Abstract of No. 144—August*, 1921.)

1. The material shall consist essentially of a distillate of coal tar, and shall be free from any admixture of petroleum or similar oils.

2. The specific gravity shall not be less than 1·015, and not more than 1·07 at 38° C. (100° F.) when compared with water at the same temperature.

3. The material shall become completely liquid on being slowly warmed to 38° C. (100° F.) with stirring, and on cooling down shall remain completely liquid after standing for two hours at 32° C. (90° F.).

4. The amount of water in the creosote shall not exceed 3 per cent.

5. When 100 c.c. measured at 38° C. (100° F.) of the dry creosote are distilled from a 250 c.c. distillation flask at such a rate that the distillation is complete in about twenty minutes, there shall distil at 760 m.m. pressure,

up to 205° C. (401° F.)	not more than	7 c.c.
„ 230° C. (446° F.)	„	40 c.c.
„ 315° C. (599° F.)	„	78 c.c.

the volumes of all fractions being measured at 38° C. (100° F.).

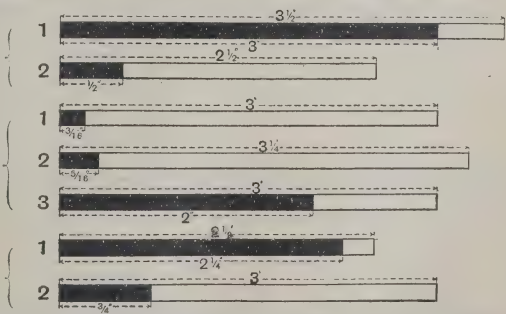
The residue above 315° C. (599° F.) shall be soft and not sticky, and its weight shall be not less than 22 gms.

6. The amount of tar acids shall be not less than 5 per cent. and not more than 16 per cent. by volume.

7. The amount of matter insoluble in benzol (benzene) shall not exceed 0·4 per cent. by weight.

B.S.S. Alternative for Scotch Creosote.

Scotch creosote shall conform to the above specification with the following exceptions:—



2. The specific gravity shall be not less than 1 at 38° C. (100° F.). In the case of the blast furnace oil the specific gravity may be lower, but shall not be less than 0·940 at 38° C. (100° F.).

5. The distillate at 315° C. (599° F.) shall be not more than 85 c.c. and the residue not less than 15 grms.

6. There shall be no upper limit to the amount of tar acids.

General Notes on Creosoting.

It is erroneous to think that in creosoting under pressure the oil penetrates throughout the timber, as this is not the case, and only occurs when timber is of small dimensions. It may be taken as a general rule in the case of Baltic Red Fir, Pitch Pine, and Oregon, that the timber showing sapwood will readily absorb the creosote, and the reverse is the case with that showing little sapwood. The heart penetration is from $\frac{1}{16}$ in. to $\frac{1}{4}$ in., according to the growth and species. In the case of Baltic Red Fir the impregnation varies considerably, according to the nature of the timber, and in all specifications for creosoting, care should be taken that the words 'average per cu. ft.' are inserted, as to obtain identical impregnation in each piece is impossible. Presuming that an average of 10 lbs. of oil per cu. ft. has been injected into the charge of timber, it does not necessarily mean that the timber which has absorbed 12 lbs. per cu. ft. will last longer than pieces with 8 lbs. per cu. ft., as the latter has a greater percentage of the heart of the tree, which prevents the admission of a large amount of creosote. The oil has done its work as far as possible, and with the smaller impregnation has considerably extended the life of the timber. The following illustrations (which are extremes) show test cores or borings taken from timber of 10 ins. by 5 ins. section showing varying penetrations, the species being creosoted separately:—

* By permission of the British Engineering Standards Association.

The cores are two-thirds the actual size, and the impregnation shown in black.

A Creosoting Plant of the foregoing description would be capable of annually treating over two million cu. ft. of the softwood species referred to, and one million cu. ft. of the hardwood, provided the works were of about 15 acres extent with 5 or 6 travelling cranes for the transportation of the timber.

To ascertain Weight of Timber-work, Timber Flooring.

Multiply breadth in feet by length in feet by the thickness in inches, and by one of the following factors, according to the material: For elm, use 2·92 lbs.; for yellow pine, 3·42 lbs.; for white pine, 2·97 lbs.; for dry oak, 4·85 lbs.

To find the Weight of Timber Beams, Posts, and Joists.

Multiply length in feet by the breadth in inches and the depth in inches, and the product by one of the following factors: For elm, ·243 lbs.; yellow pine, ·285 lbs.; white pine, ·247 lbs.; dry oak, ·404 lbs.

WEIGHT PER THOUSAND (M), FEET BOARD MEASURE.

Wood.	Dry.	Partially Seasoned.	Green.
	Lbs.	Lbs.	Lbs.
Pine and hemlock	2,500	2,750	3,000
Norway and yellow pine	3,000	4,000	5,000
Oak and walnut	4,000	5,000	—
Ash and maple	3,500	4,000	—

AVERAGE WEIGHT PER CUBIC FOOT OF WOODS.

Wood.	Weight.	Wood.	Weight.	Wood.	Weight.	Wood.	Weight.	Wood.	Weight.

Wooden Pillars.

APPROXIMATE RULE FOR THE DIMENSIONS OF WOODEN PILLARS.

W = weight in lbs., to be supported by the pillars. L = length of the pillar, in feet. D = diameter of pillar, in inches.

$$D = \sqrt[x]{L\sqrt{W}}.$$

x = ·80 for oak, ·87 for red deal.

Shingles.

1 bundle of 16-inch shingles will cover 30 sq. ft., and 1 bundle of 18-inch shingles, 33 sq. ft. when laid 5½ inches exposed to the weather.

6 pounds of fourpenny nails will lay 1,000 split-pine shingles.

Clapboards.

1 bundle laid 3½ inches exposed to the weather will cover 26 square feet. To be laid with fivepenny nails.

To find Solidity of Round Timber.

WHEN ALL DIMENSIONS ARE IN FEET.
Length × ($\frac{1}{4}$ mean girth)^2 = cubic feet.

WHEN LENGTH IN FEET, GIRTH IN INCHES
Length × ($\frac{1}{4}$ mean girth)^2 ÷ 144 = cubic feet.

WHEN ALL DIMENSIONS ARE IN INCHES.
Length × ($\frac{1}{4}$ mean girth)^2 ÷ 1728 = cubic feet.

To find Solidity of Square Timber.

WHEN ALL DIMENSIONS ARE IN FEET.
Length × breadth × depth = cubic feet.

WHEN ONE DIMENSION IS IN INCHES.
Length × breadth × depth ÷ 12 = cubic feet.

WHEN TWO DIMENSIONS ARE IN INCHES.
Length × breadth × depth ÷ 144 = cubic feet.

For BOARD MEASURE depth always equals 1 inch.

To FIND SURFACE IN SQUARE FEET, proceed as per rules for solidity of square timber.

Roofs.

LOAD ON ROOFS.

Description of Covering.	Per Square of 100 Superficial Feet.	Minimum Slope.	Description of Covering.	Per Square of 100 Superficial Feet.
	Lbs.	Degrees.		Lbs.
Lead covering weighs	784	4	Timber framing for slated or tiled roofs	560 to 672
Zinc	168	4		
Corrugated iron	336	4		
Slates	840 to 1,008	25½ to 30	Additional load for pressure of wind	4,032
Tiles	896 to 1,680	26½ to 30	Ditto for Hurricanes, say	8,960
Boarding ¾ inch thick	290	25		
Boarding 1½ inch thick	580	25		

The angle of gothic roofs should not exceed 60°.

CORRUGATED-IRON ROOFING.

BRICKWORK.

Bricks.

Description.	Size.	Weight.	Weight Per 1,000.
London stocks . . .	8¾ × 4¼ × 2¾ ins.	6·8 lbs.	60¾ cwt.
Red kiln	8¾ × 4¼ × 2¾ „	7·0 „	63 „
Welsh fire	9 × 4½ × 2¾ „	8·0 „	72 „
Paving	9 × 4½ × 1¾ „	5·0 „	45 „
Dutch clinkers . . .	6¼ × 3 × 1½ „	1·5 „	14 „

8¾ × 4¼ × 2¾ bricks, when laid in cement, occupy a space of 9 × 4½ × 3 ins. approximately.

The thickness of walls is regulated by the size of the bricks, and walls are 4½ ins. or half-brick thick, 9 ins. or 1 brick thick, 14 ins. or 1½ bricks thick. The standard thickness of reduced brickwork is 14 ins., or 1½ bricks.

1 rod of brickwork = 272 superficial ft., 1½ bricks thick ; = 11⅓ cubic yards = 306 cub. ft. ; = 235 ft. of bricks and 71 of mortar ; = 4,300 stock bricks ; = 4,500 place bricks ; = 5,370 stock bricks laid dry ; = 4,900 stock bricks laid dry in wells and circular cesspools ; = 15 tons average weight.

1 load of mortar = 1 cubic yard. 1 load of sand = 1 cubic yard. 1 bag of cement = 3 bushels. 1 sack of cement = 5 bushels.

1 rod of brickwork requires about { 1 cubic yard of stone lime, 3½ cubic yards of sand ; or 1½ yards of chalk lime, 3 yards of drift ; or 36 bushels of cement, 36 bushels of sharp sand.

1 cubic yard of brickwork requires about { 6½ cubic feet of sand. 2½ „ „ lime.

1 load of bricks = 1,000 bricks. 1,000 stock bricks, closely stacked, = 55 ft. cube. 1,000 old bricks, cleaned and loosely stacked, = 70 ft. cube. 1 foot of reduced brickwork = 16 bricks. 1 foot of superficial facing = 7 bricks. 1 foot superficial of gauged arches = 10 bricks. 1 yard superficial in bricknogging, laid flat, = 45 bricks and ⅔ cubic foot of mortar. 1 yard superficial in bricknogging, laid on edge, = 30 bricks and ⅓ cubic foot of mortar.

1 yard of paving = 36 stock bricks laid flat, = 52 bricks on edge, = 82 paving bricks on edge = 125 Dutch clinkers laid flat, = 140 Dutch clinkers on edge, = 136 Dutch clinkers laid herring-bone.

Bricks absorb one-fifth of their weight of water, but the proportion varies greatly Engineering bricks should be quite impervious to water.

A bricklayer's hod will hold 20 bricks, ⅔ cubic foot of mortar, or nearly ½ bushel.

1 rod of brickwork requires 130 gallons of water to slack the lime and mix the mortar.

In a day of 10 hours a bricklayer can lay about 1,500 to 1,600 bricks where the joints are left rough, about 1,000 when both faces are worked fair, or 500 when carefully pointed and faced with picked bricks.

For ordinary purposes, assume roughly that a bricklayer and labourer can, if they choose, turn out 2 cubic yards per diem, containing 800 bricks.

Bonds for Brickwork.

(Revised by E. A. W. Phillips, M.Inst.C.E., M.C.I.)

ENGLISH THIN-WALL BOND (fig. 669) is the simplest for all ordinary work where the walls do not exceed three brick-lengths in thickness. The heading and stretching courses always alternate in this class of bond. No stretchers occur except those seen on faces of walls. No bricks in the same course should break joint with each other. All vertical joints in any course should be covered (by one-quarter brick laps at least) by the courses above and below, and this whether offsets occur or not, or other differences in the thicknesses of the walls.

FLEMISH BOND (fig. 669A) shows headers and stretchers alternately in each course on the faces of walls. Is quite as strong as *English Thin-wall Bond*, since the quarter laps are in

FIG. 669. English Bond.

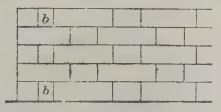

FIG. 669A. Flemish Bond.

FIG. 669B. English Thick-wall Bond

the same manner equally well maintained. *Flemish Bond* gives a better appearance for 9-inch walls, as a smoother face can be shown on both sides. In *double Flemish Bond*, both back and front of walls show Flemish Bond; in *single Flemish Bond*, one face shows Flemish, the other English, bond, as above.

ENGLISH THICK-WALL BOND (fig. 669B). In this bond, every brick in a stretcher course should be a stretcher, and every brick in a header course should be a header. The bricks not only break joint, by half their lengths, with the bricks in the same description of course (i.e., stretcher or header) next above or below them, but also break joint, by half their lengths, in the same course. This is the strongest form of bond known, and should invariably be used in heavy walling, of 3½ bricks thickness and over. The quoin difficulty is best overcome by having a few specially moulded bricks, one brick-length in length, and ¼ of a brick-length in width, and of the usual thickness. The half-bricks on faces in fig. 669B are shaded.

GARDEN-WALL BOND is the *English Thick-wall Bond* adapted to thin one-brick walling, several courses of stretchers occurring to one course of headers. The same thing may be done with *chimneys*, where the walls are 9 ins. thick.

DIAGONAL BOND and HERRING BONE BOND are only useful for paving. *English Thick-wall Bond* is stronger than either.

HEADER BOND consists entirely of headers, and is used for sharp curved or quick-sweep walls.

STRETCHER BOND, entirely of stretchers, is used in ½-brick walls of all kinds.

Other bonds, Roman bond, and the Sussex bonds, are described in 'Indian Engineering.' See also papers in the Minutes of Proceedings of Civil Engineers, vol. clxxi.

CLOSERS, *b* (figs. 669, 669A), are necessary in every alternate course to close the work on to any vertical line, or to start the bond from it; they run through the thickness of the wall.

QUEEN CLOSERS, as *b*, are ½-headers formed by cutting a brick or a half-brick, called a *bat*, longitudinally in half; ¾-stretchers, or ¾-*bats*, can be used as closers, but not so economically.

KING CLOSERS are bricks cut to a splay, so as to obtain as strong a bond as possible in closing on recessed openings, as for doors and windows.

HOOP-IRON BOND, for walls, is generally formed of hoop iron, from 1 in. to 1½ in. wide and 18 B.W.G. ($\frac{1}{20}$ in.) to 16 B.W.G. ($\frac{1}{16}$ in.) thick; it should be clean bright and bedded in cement, for if allowed to rust it swells and injures the wall; it holds better if the edges are jagged. Useful in erecting works on bad foundations, but must not be relied on to give permanent strength, unless laid as carefully as reinforcement.

WALLS.

General Rules for Building Walls.

To prevent unequal settlement the whole building should be run up together, no part rising more than about 3 ft. above the rest. Work, unless done in cement, should take its bearings gradually; at least a fortnight should be allowed for completing each storey of a high building. New work should never be bonded to old, unless built in cement. The new work should be built into a chase cut in the old work. Bricks and stones should be clean, to allow the mortar to adhere to them, and well wetted, to prevent them absorbing moisture from the mortar. Building should not be carried on in frost, but rain is good. If obliged to be carried on in frost, cement should be used, and it should be covered up with straw or boards every night, for cement which freezes before it has set is worthless.

Terra-cotta air bricks should be built into the wall, below the level of the ground-floor, for ventilation. Holes should be left in the sleeper walls.

Hollow Walls

keep houses dry, and tend to maintain a more equable temperature within them. They may be of two types: capacity walls and walls built of hollow blocks. A *cavity wall* consists of two thicknesses of brickwork separated by an air-space of 2½ ins., sometimes 4½ ins. Exterior wall, 4½ ins. thick; interior wall, of such thickness as will give the whole the necessary stability (9 ins. for two-storeyed building, 4½ ins. for ordinary one-storeyed). The two thicknesses should be tied together by bonding-ties of brick or slate, or wrought-iron ties 1 in. by $\frac{3}{16}$ in. (fig. 670), at horizontal distances of 3 ft., and alternately at vertical intervals of three courses; this requires five ties to the superficial yard. The half-brick thickness is sometimes put on the inside, in which case the weight of roof should fall on the outer thickness of wall. The air-space should be carried round all angles and up to the sides of door- and window-frames, commencing at damp-proof course, which will form its bottom, and ending in a covering course of brickwork which closes the top, so that the air-space has no communication with open air.

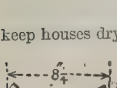

FIG. 670.

Walls of *hollow blocks* (fig. 670A) are less liable to accommodate vermin and are less risky as regards fire, as the hollow portions can be divided into a series of independent cells. The blocks may be of concrete or burned clay, the latter being usually preferred, not only on account of their porosity, but also on account of their possessing the advantageous properties of bricks, whilst being much cheaper to erect, as they commonly only measure 12 or 18 ins. by 12 ins. by 9 ins., and so are equivalent to 10 or 16 common bricks. Hollow blocks are usually rectangular tubes, which must be laid in such a manner as to provide a seal where required. Various patents have been granted for making blocks with a sealed hollow coil, but though ingenious they are scarcely a commercial success.

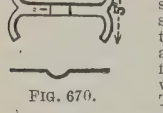

FIG. 670A.

Hollow blocks have ample strength for all ordinary requirements or brickwork, especially if laid in a 1 : 6 cement mortar. Reinforcement may be used if desired, but otherwise the hollows or cores are left 'empty.' The blocks are usually arranged with the hollow or tubular portion vertical, the joints being broken as with masonry and common brickwork. Care should be taken to arrange the detailed dimensions of the buildings so that the blocks need not be cut.

Although the hollow portion of each block may be completely seated, if desired, it is usually better to allow a small opening through which a sufficient current of air may pass, so as to secure efficient removal of moisture and to allow the air, when heated, to expand without being under pressure.

The Damp Course

is placed in a wall, 6 ins. or 9 ins. above the ground line, in order to prevent moisture from the foundations rising in the walls by capillary attraction. The following are the most satisfactory forms of damp course:—

(i) Two courses of impervious bricks (preferably 'Staffordshire blues') laid flat in a mortar composed of 1 part of Portland cement, 5 parts of sand and a waterproofing agent such as 'Pudlo' (page 400). Ordinary lime mortar is useless, as it is too porous.

(ii) One or two courses of slate or thin impervious stone laid in the cement mortar mentioned in (i).

(iii) A layer of waterproofed cement mortar (see (i)) ½ in. to 1 in. thick.

(iv) A mixture of gravel or fine grit and asphalt or tar (preferably heated together) and laid in a thickness of $\frac{5}{8}$ in. to 1 in.

(v) An elastic waterproof material such as bitumen (*George M. Callender & Co. Ltd.*), in roll form, has distinct advantages in cases where settlement in the foundations would break any rigid material, such as slates or mastic asphalt, the material being sufficiently pliable to conform to such settlement. Bitumen damp course is easily handled, even by unskilled workmen, as the material simply requires to be unrolled on to the foundations, a small lap joint being made at the end of each length. It is not necessary to seal the joint, as the weight of the next course of bricks is quite sufficient to keep the damp course in position.

(vi) Hollow tubes of stoneware or other impervious material, set vertically and laid in waterproofed cement mortar as mentioned in (i).

The essential feature of a damp course is that it must be wholly impervious to water, as otherwise it is useless. This important fact is often overlooked, as in the case where good, impervious bricks are laid in a porous lime mortar or in a porous cement-mortar.

Brick Noggings

are thin walls or partitions, usually 4½ ins. thick, constructed with vertical posts framed into top and bottom plates, filled in with brickwork in mortar, either flat or on edge. They require—

Per yard super 45 stock bricks laid flat, and ¾ cubic. ft. mortar.
" 30 " on edge, and ½ " "

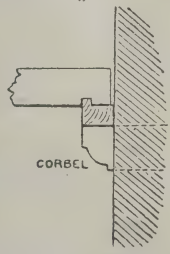

Fig. 672.

Corbelling

(Figs. 671 and 672) keeps joists clear of masonry, and prevents walls from being weakened by the insertion of timber; in brickwork the projections of the courses should not be more than a quarter brick. When great strength is required, they may project only one-eighth brick. Stone corbels should be of York or equally hard stone, about 4 feet from centre to centre, according to depth of wall plate.

Coping.

If of brick, should be the hardest and least porous, set in cement. In stone, should be of as long stones as possible. Fig. 673 shows brick-on-edge coping. The course A may be two courses of

Fig. 673.

Fig. 674.

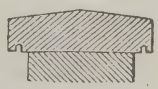

Fig. 675.

tiles laid in cement, breaking joint, called *tile-creasing*. Fig. 674 shows another form; but moulded brick copings are preferable, being made of various patterns to suit walls of different thicknesses. Fig. 675 is a stone saddle-back coping.

Thickness of Walls.

In walls not more than 30 feet high top storey may be 8½ inches thick.

Thickness of higher walls at top and 16 feet below = 13 inches.

From 16 feet below top to base the wall not to be less than the space contained in the two straight lines drawn from each side of the walls, at the base, to each side of the wall 16 feet below the top.

The thickness to be in no case less than one-fourteenth of the height of the storey; but any additional thickness may be confined to piers whose collective width equals one-fourth length of wall. Footings to be double the width of the base, diminishing in regular offsets half the width of their height.

Cross-walls to be two-thirds of the thickness of the external or party walls, but never less than 8½ inches.

Thickness of Walls of Buildings (Gwilt's Rule).

H = height of wall; L = length between party walls; D = diagonal of face of wall = $\sqrt{H^2+L^2}$; T = thickness of wall; all in feet.

Then

$$T = \frac{HL}{nD},$$

where n = 22 for dwelling-houses of brick, 20 for warehouses of brick, 18 for public buildings of brick.

When the height of wall is less than half its length, then n may be increased to 27, 23, and 20 respectively.

The dimensions in the following Tables may be safely adopted.

THICKNESS OF BRICK EXTERNAL WALLS FOR DIFFERENT SORTS OF ONE-STOREYED BUILDINGS.

Description.	Main Wall.	Piers 2 ft. 3 in. Wide, 10 Feet from Centre to Centre.
Single-storeyed buildings up to 10 feet high and 30 feet wide, with cross-walls every 14 feet	9 inches	
Ditto, with principals, but without cross-walls, any length	9 „	14 inches
Ditto, over 10 feet and not exceeding 20 feet high, with principals, but not cross-walls, any length, width up to 30 feet	14 „	18 „

NOTE.—Where it is not considered advisable to have piers, the greater thickness, *i.e.*, the thickness of the piers, should be adopted.

THICKNESS OF BRICK EXTERNAL WALLS FOR DIFFERENT SORTS OF TWO-STOREYED BUILDINGS.

Description.	Lower Storey.	Upper Storey.
Two-storeyed buildings with cross-walls every 14 feet up to 30-feet span	14 inches	9 inches
Ditto, 30-feet span, with principals, but not cross-walls .	18 „	14 „

Stonework should be, as a rule, one-third thicker than brickwork.

For inhabited buildings the walls are better built hollow.

When concrete (1 Portland cement, 6 ballast) is used, the wall is usually about one-third thicker than brickwork.

Rules for the Walls of Buildings not Public and not of the Warehouse Class.

(*London Building Act*, 57 & 58 *Vict.* 1894.)

According to this Act the external and party walls of dwelling-houses must be made throughout the different storeys of the thickness shown in the following Table, arranged according to the heights and lengths of the walls, and arranged for walls up to 120 feet in height, and supposed to be built of bricks not less than 8½ inches long or of stone or other blocks of hard and incombustible substance, the beds or courses being horizontal, the heights of the storeys being subject to the conditions given after the Table.

TABLE I.

1. Height up to 25 Feet.	Length up to 30 Feet. Not more than two storeys.	Length unlimited. More than two storeys.	
	From base to top of wall, 8½ ins.	Wall below topmost storey, 13 ins. Topmost storey, 8½ ins. Remainder 8½ ins.	
2. Height up to 40 feet.	Length up to 35 Feet.	Length unlimited.	
	Wall below two topmost storeys, 13 ins. Remainder, 8½ ins.	One storey, 17½ ins. Rest of wall below topmost storey, 13 ins. Remainder, 8½ ins.	
3. Height up to 50 Feet.	Length up to 30 Feet.	Length up to 45 Feet.	Length unlimited.
	One storey, 17½ ins. Rest of wall below topmost storey, 13 ins. Remainder, 8½ ins.	Two storeys, 17½ ins. Remainder, 13 ins.	One storey, 21½ ins. One storey, 17½ ins. Remainder, 13 ins.

TABLE I. (*continued*).

4. Height up to 60 Feet.	Length up to 45 Feet. Two storeys, 17½ ins. Remainder, 13 ins.	Length unlimited. One storey, 21½ ins. Two storeys, 17½ ins. Remainder, 13 ins.
5. Height up to 70 Feet.	Length up to 45 Feet. One storey, 21½ ins. Two storeys, 17½ ins. Remainder, 13 ins.	Length unlimited. Each storey below uppermost two storeys to be increased 4½ ins. beyond thicknesses for length up to 45 feet.
6. Height up to 80 Feet.	Length up to 45 Feet. One storey, 21½ ins. Three storeys, 17½ ins. Remainder, 13 ins.	Length unlimited. Each storey below uppermost two storeys to be increased 4½ ins. beyond thicknesses for length up to 45 feet.
7. Height up to 90 Feet.	Length up to 45 Feet. One storey, 26 ins. One storey, 21½ ins. Three storeys, 17½ ins. Remainder, 13 ins.	Length unlimited. Each storey below uppermost two storeys to be increased 4½ ins. beyond thicknesses for length up to 45 feet.
8. Height up to 100 Feet.	Length up to 45 Feet. One storey, 26 ins. Two storeys, 21½ ins. Three storeys, 17½ ins. Remainder, 13 ins.	Length unlimited. Each storey below uppermost two storeys to be increased 4½ ins. beyond thicknesses for length up to 45 feet.
9. Height up to 120 Feet.	Length up to 45 Feet. One storey, 30 ins. Two storeys, 26 ins. Two storeys, 21½ ins. Three storeys, 17½ ins. Remainder, 13 ins.	Length unlimited. Each storey below uppermost two storeys to be increased 4½ ins. beyond thicknesses for length up to 45 feet.

10. If any storey exceeds in height sixteen times the thickness prescribed for the walls of such storey in the above Table, the thickness of each external and party wall throughout such storey shall be increased to one-sixteenth part of the height of the storey, and the thickness of each external and party wall below that storey shall be increased to a like extent; but any such additional thickness may be confined to piers, properly distributed, of which the collective widths amount to one-fourth part of the length of the wall.

11. No storey enclosed with walls less than 13 inches in thickness shall be more than 10 feet in height between the floor and the ceiling thereof, or between the floor and the tie of the roof.

12. All buildings, excepting public buildings and such buildings as are in the Act defined to be buildings of the warehouse class, shall, as respects the thickness of their walls, be subject to the foregoing rules.

Rules for the Walls of Buildings of the Warehouse Class.

(London Building Act.)

The external and party walls of buildings of the warehouse class must at the base be made of not less thickness than that shown in the following Table, arranged for walls up to 120 feet in height, and supposed to be built of bricks not less than 8½ inches, or of stone or other blocks of hard and incombustible substance, the beds or courses being horizontal.

TABLE II.

1. Height up to 25 Feet.	Length unlimited. — Base, 13 inches.		
2. Height up to 30 Feet.	Length up to 45 Feet. — Base, 13 ins.	Length unlimited. — Base, 17½ ins.	
3. Height up to 40 Feet.	Length up to 35 Feet. — Base, 13 ins.	Length up to 45 Feet. — Base, 17½ ins.	Length unlimited. — Base, 21½ ins.
4. Height up to 50 Feet.	Length up to 30 Feet. — Base, 17½ ins.	Length up to 45 Feet. — Base, 21½ ins.	Length unlimited. — Base, 26 ins.
5. Height up to 60 Feet.	Length up to 45 Feet. — Base, 21 ins.	Length unlimited. — Base, 26 ins.	
6. Height up to 70 Feet.	Length up to 45 Feet. — Base, 21½ ins.	Length unlimited. — Length to be increased in thickness from the base up to within 16 ft. from the top of the wall by 4½ ins.	
7. Height up to 80 Feet.	Length up to 45 Feet. — Base, 21½ ins.	Length unlimited. — Length to be increased in thickness from the base up to within 16 ft. from the top of the wall by 4½ ins.	
8. Height up to 90 Feet.	Length up to 45 Feet. — Base, 26 ins.	Length unlimited. — Length to be increased in thickness from the base up to within 16 ft. from the top of the wall by 4½ ins.	
9. Height up to 100 Feet.	Length up to 45 Feet. — Base, 26 ins.	Length unlimited. — Length to be increased in thickness from the base up to within 16 ft. from the top of the wall by 4½ ins.	
10. Height up to 120 Feet.	Length up to 45 Feet. — Base, 31 ins.	Length unlimited. — Length to be increased in thickness from the base up to within 16 ft. from the top of the wall by 4½ ins.	

11. The thickness of the wall at the top, and for 16 feet below the top, shall be 13½ inches; and the intermediate parts of the wall between the base and such 16 feet below the top shall be built solid throughout the space between straight lines drawn on each side of the wall, and joining the thickness at the base to the thickness at 16 feet below the top; nevertheless, in walls not exceeding 30 feet in height the walls of the topmost storey may be 9 inches thick, provided the height of that storey does not exceed 10 feet.

12. If in any storey of a building of the warehouse class the thickness of the wall, as determined by the foregoing Table, is less than one-fourteenth part of the height of such storey, the thickness of the wall shall be increased to one-fourteenth part of the height of the storey, and the thickness of each external and party wall below that storey shall be increased to a like extent; but any such additional thickness may be confined to piers, properly distributed, of which the collective widths amount to one-fourth part of the length of the wall.

13. The thickness of any wall of a building of the warehouse class, if built of materials other than such bricks as aforesaid, shall be deemed to be sufficient if made of the thickness required by the above Tables, or of such other thickness as may be approved by the County Council.

MISCELLANEOUS.

(London Building Act.)

The thickness of a cross-wall shall be two-thirds of the thickness hereinbefore required for an external or party wall of the same dimensions, and belonging to the same class of buildings, but never less than 8½ inches; and no wall subdividing any building shall be deemed to be a cross-wall unless it is carried up to the floor of the topmost storey, and unless in each storey the aggregate extent of the vertical faces or elevations of all the recesses and that of all the openings therein taken together does not exceed one-half of the whole extent of the vertical face or elevation of the wall.

Rules for Structural Steelwork for Buildings.

London County Council Act (1909).

Part IV., section 22, of the London County Council (General Powers) Act, 1909, which came into operation August 16, 1909, makes certain provisions, summarised below, with respect to buildings of iron and steel skeleton construction, and with the foundations, walls, floors, staircases, etc., of such buildings.

(1) All rolled steel shall comply with the British standard specification for structural steel for bridges and general building construction, and every pillar or girder shall be of iron or steel or any other metal which may be standardised by the Engineering Standards Committee.*

(2) The skeleton framework of a building, together with the party wall or walls upon which such framework bears, shall be capable of safely and independently sustaining the whole dead load and superimposed load bearing thereon.

(3) Pillars in external walls to be completely enclosed and protected from the action of fire by a casing of brickwork, etc., or incombustible material, at least 4 inches thick, properly bonded.

(4) Girders in external walls to be similarly encased with brickwork or other incombustible material at least 4 inches thick, properly secured to the adjoining work. The casing on the underside of such girders and to the edges of the flanges, plates, and angles may be not less than 2 inches thick.

(5) All other pillars and girders to be protected from the action of fire by being encased to the satisfaction of the district surveyor to a thickness of not less than 2 inches. The casing on the upper surface of girders and on the lower surface of subsidiary joists may be not less than 1 inch. Wood firrings must not be used in connection with any casing. This subsection does not apply in the case of buildings of only one storey and not more than 25 feet in height.

(6) Girders to be secured against buckling if the length of the girder exceeds thirty times the width of the compression flange. The web of every girder to be secured against buckling when the depth of the web exceeds sixty times the thickness.

(7) The span of a girder must not exceed twenty-four times the depth of the girder unless the calculated deflection is less than one four-hundredth part of the span.

(8) Two or more girders arranged alongside and closely adjacent to one another, so as to act together, must be fixed together by means of iron separators and bolts, or in any efficient manner approved by the district surveyor. Separators or other members acting as separators must not be placed at a distance apart exceeding five times the depth of the girders, and must be placed immediately over all supports and immediately under all concentrated loads.

(9) Girders for supporting external walls must be placed at the floor level of a storey or not more than 5 feet above or below floor level.

(10) Rivets must be used where reasonably practicable. Where bolts are used they must extend through the full thickness of the nuts, and the nuts must be so secured as to avoid risk of their becoming loose. The distance from the edge of a rivet or bolt hole to the edge of the member may not be less than the diameter of the rivet or bolt. Rivets must be so placed that their centres shall not be closer together than three times the diameter of the rivets. The pitch of rivets measured in a continuous straight line in girders, pillars, and roofwork must not exceed sixteen times the thickness of the thinnest member through which they pass.

(11)—(A) An external wall may not be less than 8½ inches thick for the topmost 20 feet of its height, and 13 inches for the remainder of its height below such topmost 20 feet. A less thickness may be allowed in any case in which under the London Building Act, 1894, such less thickness is prescribed.

(B) All party walls shall be of the thicknesses prescribed by the principal Acts.

(C) All brickwork and work in which terra-cotta, concrete, or other similar materials are used must be executed in Portland cement (British standard specification) mortar bedded close up to the metal framework without intervening cavity, and all joints must be made full and solid. In party walls (exclusive of any parts thereof immediately surrounding metal framework), or other internal brickwork not constructed to carry loads or stresses, lime mortar may be used.

(12)—(A) No plate or bar in any steel or wrought-iron pillar may in any part be less than ¼ inch thick, and the bases of all such pillars must be at right angles to the axis.

(B) Joints in such pillars must be close-butted with riveted cover-plates, and joints between such pillars must be properly fixed and made, and, unless unavoidable, no joint may be made between such pillars except as near as practicable to the level of a girder secured to such pillars.

* Now British Engineering Standards Association.

(c) The foot of every such pillar must have a proper base-plate riveted thereto with sufficient gusset pieces to distribute properly the load on the foundations, and the gusset pieces shall have sufficient rivets to transmit the whole of the load on to the base-plates.

(d) Where any pillars are built up hollow the cavities must be filled with concrete or be covered at both ends by metal plates riveted thereto.

(13)—(a) The width of cast-iron pillars may not be less than 5 inches, and the metal may not be in any part less than $\frac{3}{4}$ inch thick or one-twelfth of the least width of such pillar (whichever is the greater).

(b) The cap and base of every pillar must be in one piece with the pillar, or be connected thereto with a turned and bored joint.

(c) The ends of all pillars must be at right angles to the axis.

(d) Joints between such pillars shall be at or as near as practicable to the level of a girder secured to such pillars, and shall be fixed with not fewer than four bolts of not less diameter than the least thickness of metal in the pillar. If more than four bolts are used the diameter of the bolts may be reduced proportionately, but no bolt may be less than $\frac{3}{4}$ inch in diameter.

(e) The base of every such pillar shall have sufficient area to distribute properly the load on the foundations.

(14) The base of every pillar shall be bedded so that the load may be transmitted uniformly to the foundations.

(15) The stress in any metal interposed between the ends of a superimposed pillar and a pillar beneath must not exceed the stress on the superimposed pillar, and the least width across such interposed metal may not be less than the least width of the superimposed pillar.

(16) All floors and staircases (together with their enclosing walls) shall be constructed throughout of fire-resisting materials and be carried upon fire-resisting supports.

(17) All structural metalwork comprised in the skeleton framework of a building must be cleaned of all scale, etc., and be coated with one coat of boiled oil, tar, or paint before erection, and after erection shall receive at least one additional coat. Where embedded or encased in brickwork or other incombustible materials one coat of Portland cement wash applied after erection may be used.

(18)—(a) The dead load of a building consists of the actual weight of walls, floors, roofs, partitions, and all other permanent construction comprised in such building.

(b) The superimposed load in respect of a building consists of all other loads.

(c) For calculating the loads on constructions carrying loads in buildings the superimposed load on each floor and on the roof shall be estimated as equivalent to the following dead load :—

For a floor intended to be used for the purposes of human habitation or domestic purposes, 70 lbs. per square foot of floor area ;

For a floor intended to be used for the purpose of an office, or for any similar purpose, 100 lbs. per square foot.

For a floor intended to be used for the purpose of a workshop or retail shop, 112 lbs. per square foot ;

For every floor in a building of the warehouse class not intended to be used for any of the purposes aforesaid, not less than 224 lbs. per square foot. In every building of the warehouse class a notice shall be exhibited in a conspicuous place on each storey stating the maximum superimposed load per square foot which may be carried on such floor ;

For a roof the plane of which inclines upwards at a greater angle than 20° with the horizontal, the superimposed load (which includes wind pressure) shall be estimated at 28 lbs. per square foot of sloping surface ;

For all other roofs the superimposed load shall be estimated at 56 lbs. per square foot measured on a horizontal plane.

If the superimposed load on any floor or roof is to exceed that specified, such greater load shall be provided for pursuant to subsection (2).

In the case of any floor intended to be used for a purpose for which a superimposed load is not specified, the superimposed load shall be provided for pursuant to subsection (2).

(19) For calculating the total load to be carried on foundations, pillars (including brick pillars), piers, and walls in buildings of more than two storeys in height, the superimposed loads for the roof and topmost storey shall be calculated in full in accordance with the last preceding subsection ; but for the lower storeys a reduction may be allowed, as follows :—

For the storey next below the topmost storey a reduction of 5 per cent. of the full superimposed load ;

For the next succeeding lower storey a reduction of 10 per cent. of the full superimposed load, and for each succeeding lower storey a further reduction of 5 per cent. of the full superimposed load. Provided always that the total reduction in respect of any storey shall not exceed 50 per cent. of the full superimposed load for such storey ;

No such reduction as aforesaid shall be allowed in the case of a building of the warehouse class.

(20) All buildings shall be so designed as to resist safely a wind pressure in any horizontal direction of not less than 30 lbs. per square foot of the upper two-thirds of the surface of such buildings exposed to wind pressure.

(21)—(a) The working stresses on pillars of cast iron or mild steel due to the loads thereon (other than stresses induced by wind pressure) shall not exceed those specified in the two following tables, according to the several ratios therein specified, or a proportionate load for other ratios :—

Cast-iron Pillars.

Ratio of Length to least Radius of Gyration.	Working Stresses in Tons per Square Inch of Net Section.		
	Hinged ends.	One end hinged and one end fixed.	Both ends fixed.
20	3·5	4·0	4·5
30	3·0	3·5	4·0
40	2·5	3·0	3·5
50	2·0	2·5	3·0
60	1·5	2·0	2·5
70	1·0	1·5	2·0
80	0·5	1·0	1·5

Mild Steel Pillars.

Ratio of Length to least Radius of Gyration.	Working Stresses in Tons per Square Inch of Section.		
	Hinged ends.	One end hinged and one end fixed.	Both ends fixed.
20	4·0	5·0	6·0
40	3·5	4·5	5·5
60	3·0	4·0	5·0
80	2·5	3·5	4·5
100	2·0	3·0	4·0
120	1·0	2·5	3·5
140	0·0	2·0	3·0
160		1·0	2·5
180		0·0	1·5
200			0·5
210			0·0

(B) The working stresses on wrought-iron pillars due to the loads (other than wind-pressure stresses) may not exceed two-thirds of the stresses specified for mild steel pillars.

(C) Any pillar eccentrically loaded must have the combined stresses resulting from such eccentricity at any part added to all other stresses at that part, and the sum of the stresses may in no case exceed the working stresses specified.

Provided that working stresses exceeding those specified in paragraphs (A), (B), and (C) by not more than 25 per cent. may be allowed where such excess is due to wind pressure.

(D) The eccentric load of a pillar may be considered to be distributed uniformly over its cross-section area at the next lower level at which it is fixed and secured in the direction of eccentricity.

(22) The working stresses of iron and steel (except in the case of pillars as hereinbefore provided) may not exceed the following :—

Metal.	Working Stresses in Tons per Square Inch.			
	Tension.	Compression.	Shearing.	Bearing.
Cast iron	1·5	8	1·5	10
Wrought iron	5	5	4	7
Mild steel	7·5	7·5	5·5	11

(23) Any rivet used in double shear the working shear may not exceed one and three-quarter times the shear allowed on a rivet used in single shear.

(24) The pressures of foundations on the natural ground may not exceed the following :—

Material.	Tons per Square Foot.
Natural bed of soft clay or wet or loose sand	1
Natural bed of ordinary clay or confined sand	2
Natural bed of compact gravel, London blue clay, or chalk	4

(25) The pressure on concrete foundations may not exceed 12 tons per square foot.

(26) No disengaged brick pillar without lateral supports may have a height of more than six times its least width; but a pillar with lateral supports may have a height between such supports not more than twelve times its least width, but in no case less than 13½ inches.

(27) The pressure on any brickwork may not exceed the following :—

Material.	Tons per Square Foot.
Blue brick in cement mortar	12
Hard brick (including London stock) in cement mortar	8
Ordinary brick in cement mortar	5

(28) The Council may prescribe the materials and the proportions to be used in concrete provided under the provisions of this section.

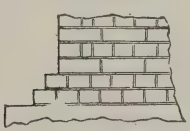
(29) It shall be lawful to make any addition, alteration, or do other work upon a building in accordance with this section, provided that the loads and stresses in a building so altered are transmitted from the roof to the foundations by a skeleton framework of metal, or partly by a skeleton framework and a party wall, and the foregoing provisions shall apply as if the part so altered were a separate building.

Foundations.

Brick walls are made wider at the base, in order to spread the weight of the building over a larger area and produce an equality of settlement.

Figs. 676 to 682 show sections of footings (the wide courses at the base of a wall) of walls in English bond from one to three bricks in thickness. Trenches are excavated for beds of concrete usually from 2 feet to 7 feet in depth, and 12 inches wider than base of footings (6 inches on each

FIG. 676. Elevation.



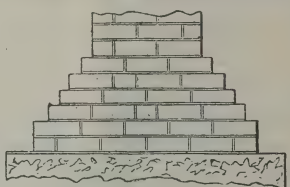


FIG. 677. Section.

FIG. 678. Frontage for 2½-Brick Wall.

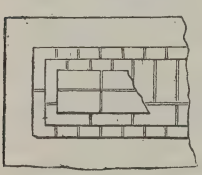

FIG. 679. Plan.

FIG. 680.

FIG. 681.

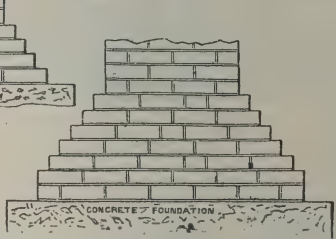

FIG. 682.

side). If the site on which a building is to be built be gravel, sand, or natural virgin soil, no concrete bedding must be used; but otherwise the whole site should be covered with a layer of concrete not less than 6 inches thick.

The foundations of the walls of a building should be on a bed of good concrete not less than 9 inches thick, and projecting at least 4 inches on each side of the lowest course of footings of walls. If the site be upon a natural bed of gravel, concrete is not required.

MASONRY.

Lifting Stones.

There are various ways of laying hold of stones which are too heavy to be moved by hand. The following are those most frequently used :—

1. By a pair of nippers or iron claws or hooks, as in fig. 683, the ends of which catch in holes

made, one in each side of the block, in the same vertical plane as, and at a convenient distance above, the centre of gravity of the block. 2. By a *Lewis*, or iron dovetail, as in fig. 684, made in three pieces, the two outer ones being first dropped into a corresponding dovetailed hole cut in the stone directly over its centre of gravity, then the centre-piece slipped in between them, the suspending-tackle put in its place, and finally a bolt passed through the whole and keyed up. 3. By two curved iron plugs, with a chain passing through eyes in their heads, placed in a dovetailed hole directly over the centre of gravity of the stone, as shown in fig. 685. 4. By an iron conical plug, with an eye at the top for a chain or hook to pass through, placed in a rather

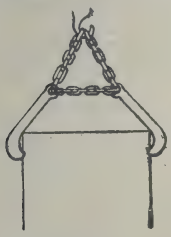

FIG. 683.

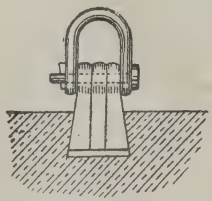

FIG. 684.

larger conical hole directly over the centre of gravity of the stone, with an iron wedge curved so as to fit the plug and the circumference of the hole, tightly driven in by its side, as shown in fig. 686. This plug was used for setting the heavy granite coping on the Thames Embankment

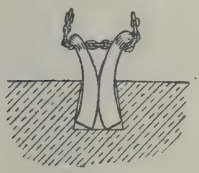

FIG. 685.

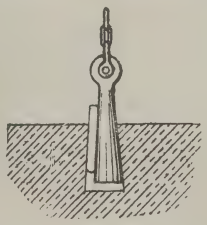

FIG. 686.

wall. 5. By a single iron plug, very slightly tapered, and driven into a cylindrical hole directly over the centre of gravity of the stone. By this simple means hard stones, such as granite, may be lifted with ease, a few side taps being sufficient to loosen the plug when required to be withdrawn.

Setting Stones.

All stones, except under peculiar circumstances, should be laid on their natural or quarry beds, or with their natural beds as far as possible perpendicular to the pressures they have to bear.

All dry and porous stones should be well wetted before being laid, so as not to absorb the moisture required for the proper setting of the mortar. Iron should never be placed in contact with stonework where, by rusting, it might disfigure it with stains, or split the stone, either by its increase in bulk during the process of oxidation, or by its expanding and contracting under the influence of heat and cold.

Descriptions of Masonry.

There are three descriptions of masonry in ordinary use, viz. :—

Rubble. Block-in-Course. Ashlar.

If the stone at disposal is thinly bedded, rough, or intractable, it should be used as *Rubble work*; if obtainable in blocks, and more or less easily wrought, it should be used as *Block-in-Course* or *Ashlar*, according to circumstances.

The various systems are illustrated by figs. 687 to 695.

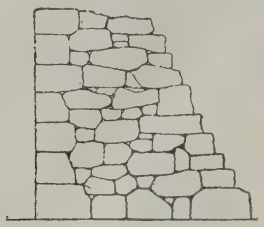

FIG. 687. Common, Rough, Uncoursed, or Random Rubble.

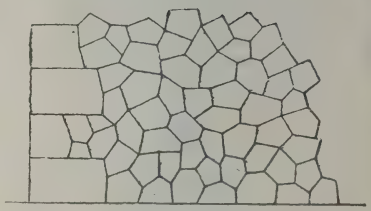

FIG. 688. Random Rubble, with hammer-dressed joints and no spalls on face.

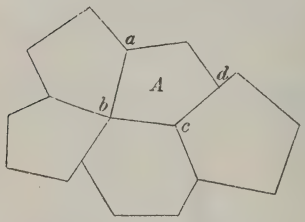

FIG. 689. Hammer-dressed Joints for Random Rubble.

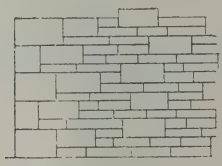

FIG. 690. Irregular-coursed, Random-coursed, Snecked, or Squared Rubble.

FIG. 691. Built up to Courses.

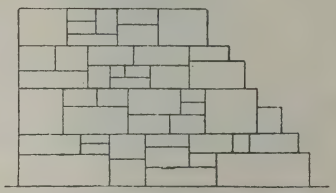

FIG. 692. Built up to Courses, with beds horizontal and joints vertical.

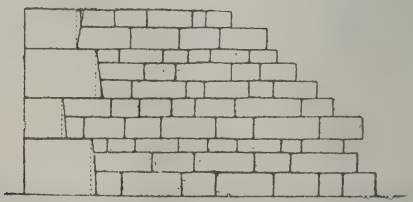

FIG. 693. Coursed Rubble.

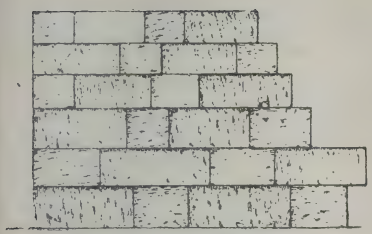

FIG. 694. Block-in-Course.

FIG. 695. Ashlar.

RUBBLE MASONRY.

The best stones for rubble masonry are those that scabble freely, and such as lie in 4 or 5 inch beds. Basalts and stones of a crystalline structure are troublesome to use, as they fly under the hammer ; but granite and sandstones work in well.

Rubble may be either *uncoursed*, *irregular*, or *random-coursed*, *worked up to courses*, or *coursed*, chiefly depending upon the character of the stone at disposal ; some stones, such as Kentish rag, from their intractable nature, and the absence of any distinct lines of bedding, are specially adapted for *uncoursed* rubble, whilst others readily work into courses, and therefore should be used as *coursed* rubble.

In common, rough, uncoursed, or random rubble (fig. 687) the stones are laid at random, without being brought up to any level courses, the only tools required being a trowel, waller's hammer, and plumb or battering rules, as the case may require.

One bond stone should be used to at least every yard super of the face, and these should run about two-thirds to three-fourths through the wall, alternately from the opposite sides ; this, in the case of dwelling-houses, diminishes the chances of damp being transmitted to the interior, and is in all cases much preferable to a smaller number of *through* stones. In boundary and similar walls *through* stones may, of course, be used. In thick walls, such as piers, abutments, and retaining-walls, the bond stones should tail into the work as far as possible ; and the whole should be bonded together in the best way the sizes of the blocks will admit of.

It is necessary to see the bond stones actually built into the wall, for builders are apt to set large stones on edge, running only 3 or 4 inches into the wall, instead of true bond stones—a trick which cannot well be detected after they have once been covered up. In random work (figs. 688 and 689) the stones cleave into irregular shapes, and are fitted closely together. Thus, in order to get A (fig. 689) into place the angles *abc*, *deb*, are taken with the mason's bevel, and the joints are hammered and punched to fit truly. This is the most expensive kind of rubble work, and requires much more skill to build properly than any other class of rubble walling.

If the rubble stone is distinctly bedded, the beds varying much in depth, and often running very thin, the stones should be put together as in fig. 690, in what is called *irregular* or *random-coursed* rubble. The joints in this case are not necessarily vertical ; but in a superior class of the same work all the joints are specified to be vertical and the beds horizontal, by which a more regular appearance is given to the work. The stones are all shaped and roughly squared as required, and hammer or axe faced, in the gross, ready for the waller to set in the wall. This class of masonry is very bold and effective for engineering purposes, when a good proportion of large stones are used, roughly hammer-dressed on face.

Both of the kinds of rubble masonry just described are very commonly worked up at intervals, with the line and level, to level courses, either regular or irregular in depth, the latter being preferable on account of its appearance and more suitable to the irregular sizes of the stones used. From 18 to 14 inches are the ordinary depths of the courses, according to the nature of the stone. Figs. 691 and 692 show both common and irregular coursed rubble worked up to courses ; the latter being also called *coursed header work* when the headers, occurring at intervals, run the full depth of the course. In fig. 693 a superior class of work is shown, the joints being all vertical, by which means a more regular appearance is obtained.

Rankine's 'Civil Engineering,' speaking of coursed rubble (such as fig. 693), says : '*One-fourth part* at least of the face in each course should consist of bond stones or headers, each header to be of the entire depth of the course, of a depth ranging from one and a-half times to double that depth, and of a length extending into the building to from three to five times that depth, as in ashlar. These headers should be roughly squared with the hammer, and their beds hammer-dressed to approximate planes ; and care should be taken not to place the headers of successive courses above each other, for that arrangement would cause a deficiency of bond in the intermediate parts of the course. Between the headers each course is to be built of smaller stones, of which there may be one, two, or more in the depth of the course. These are sometimes roughly squared, so as to have vertical side-joints ; sometimes the stones are taken as they come, so that the side-joints are irregular ; but no side-joint should form an angle with a bed-joint sharper than

60°. Care should be taken, not only that each stone shall rest on its natural bed, but that the sides parallel to that natural bed shall be the largest, so that the stone may be flat, and not be set on edge or on end. However small and irregular the stones may be, care should be taken to make the course break joint. Hollows between the larger stones should be carefully filled with smaller stones, completely embedded in mortar.'

The same authority gives the resistance of good coursed rubble masonry to crushing at about four-tenths of that of single blocks of the stone it is built with.

Coursed, or regular coursed rubble, as shown in fig. 693, is applicable where the beds, though thin, are pretty regular, so that a sufficient number of stones of a uniform depth can be got to allow of their being laid in regular courses of one stone only in depth. Larger stones, often of cut stone, equal in depth to two or three courses of the rubble work, are generally used at the quoins.

Whenever cut-stone is used in connection with rubble work, as at the quoins of a building, the ends adjoining or tailing into the rubble should never be cut square, but be left comparatively rough, so as to harmonise with the masonry in the body of the wall, and not appear as if cut off from it by straight lines.

Dry-walling is the simplest class of rubble work, and consists of stones roughly hammered, and bedded by pinning with spalls, without any mortar. It requires considerable skill to build properly, as its stability depends entirely on the firm bedding and bonding of the different stones. It is chiefly used for fencing land, for railway and canal embankments and cuttings, or at the backs of retaining-walls, to diminish the pressure of the earth on them, and to allow of water finding its way down to the drains below. Such walls—which are generally about 5 feet high, increasing in thickness towards the bottom, and averaging about 18 inches thick—are usually built to lines strained between trestles (fig. 696), in order to avoid plumbing the face.

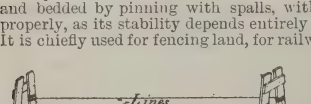

FIG. 696.

Dry-rubble walling is generally built in courses about 12 inches high, and should have a waterproof top, or *coping*, to keep the water from getting into the body of the work and bursting it in frosty weather. The coping may be made of stones laid on edge in mortar, bituminous concrete, or, for want of anything better, clay puddle, or even sods.

When the stones come out in thin slabs the walls may be specified to be built of 'good sound, flat bedded stones of a fair average size (none less than 6 inches broad across the narrowest part), set dry, and coped with stones, not less than 9 inches deep, set on edge; each coping stone to extend across the full breadth of the wall, and to be properly set in good hydraulic mortar.' A high joint with a projecting ledge is very frequently used to mark the joints of rubble work; this is a bad system, and is sure to peel off under the influence of wet and frost.

A cubic yard of rubble masonry will, as a rule, require $\frac{1}{3}$ cubic yard of mortar and $1\frac{1}{3}$ cubic yard of stone.

BLOCK-IN-COURSE MASONRY.

Block-in-Course (fig. 694, page 387) is a term applied by engineers to a class of masonry much used in piers, abutments, wing walls, &c., when there is a suitable stone in the district and good solid work is required. The stones are all squared and brought to good fair joints, the faces being more or less worked, according to taste, but generally merely hammer-dressed; and the courses consist of single stones only in depth. It chiefly differs from ashlar in the smaller size of the stones and depth of the courses, the stones at command being—ordinarily rougher and more thinly bedded—chiefly *shoddies*, or stones under 12 inches deep, whereas *ashlar* blocks range, as a rule, from 12 inches to 14 inches in depth.

The best stone for the purpose is a hard, self-bedded stone which will work easily into courses from 3 inches to 10 inches or 12 inches in depth, the length of each stone being four or five times its depth. No attention is paid to uniformity in the depth of the courses.

ASHLAR MASONRY

The term *ashlar* is applied to masonry built up of a thick-bedded stone which admits of being scabbled, or sawn into square blocks of given dimensions. It is also used to denote roughly-squared blocks of stone over 12 inches deep, as delivered from the quarry or stonecutter, or as prepared for setting. Ashlar work (fig. 695, page 387) is built in courses of uniform, or nearly uniform, depth—generally from 10 inches to 14 inches—ranging throughout with the quoins and dressings. It goes by different names according to the face put upon the stone, from quarry-pitched or rock ashlar up to wrought ashlar.

No stone should be laid in mortar without being first fitted into place, and any irregularities in shape corrected. Large ashlars are first accurately fitted into place, and then set on a bed of mortar carefully spread out to receive them; after which the vertical joints have to be filled by stopping them up on the outsides with cement, and pouring in cement or mortar grout, which should be worked about with a piece of hoop iron, so as to ensure its completely filling the joints. The beds and joints are worked to plane surfaces, so as to allow of close-fitting joints. These surfaces should not be too smooth, otherwise the mortar will not adhere so well to the stones, but in good work should be true enough to allow of joints not over $\frac{1}{8}$ inch thick; they are generally

either left as they come from the saw (if sufficiently true), or taken out of winding by running chisel draughts round the margins, and dressing them down with the point, as in half-plain work, taking off any parts left projecting beyond the level of the chisel draughts with a chisel.

Proportions for Stones, Bond, &c.

In both block-in-course and ashlar masonry it is necessary to proportion the length, breadth, and thickness of the stones according to their hardness, in order to guard against their breaking across. Rankine says that in the weaker sandstones and granular limestones the length of a stone should not exceed three times its depth, nor the breadth one and a-half to double its depth. In harder stones—such as require 2½ or more tons to the inch to crush them—the length may be four or five times the depth, and the breadth three times the depth.

The best bond in masonry is that which shows on the face of the work alternate headers and stretchers in each course, as in Flemish bond in brickwork, each header coming over the centre of a stretcher in the course below. In such work one-third of the face consists of headers, if the length of the stretchers is twice the breadth of the headers; but as stones are rarely cut to exactly the same dimensions, it may be laid down that not less than one-fourth of the face of the wall should consist of headers, and that the stones should break joint from one to one and a-half times the depth of a course.

The thickness of the joints will vary from ½ to ⅛ inch, according to the smoothness of, or amount of work bestowed upon, the beds, as it must be sufficient to transmit the pressures from stone to stone without permitting of actual contact at any point of their surfaces.

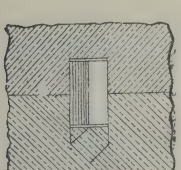

FIG. 696A.

Dowelling.

For securing stones in places where the adhesion of the mortar or cement is not sufficient *dowelling* is the best method. Fig. 696A shows a method of doing this. It consists in making exactly opposite each other, in the two stones two holes, either circular or square in section, and fitting into them a dowel or pin. These may preferably be of good hard slate, run with either brimstone or cement.

Measurement and Valuation of Masonry.

In districts where stone abounds, and forms the principal material for building purposes, ordinary walls are built of rubble stone, and measured by the cubic yard, or some other local standard, such as, in Ireland, by the running perch (21 feet), of a given height and thickness, or by the square perch of 21 feet super, at a standard thickness of 18 inches. In the West of England the square perch is employed, of 18 feet super, at a standard thickness of 2 feet, to which walls of any thickness are reduced; or the price per perch may vary with the thickness of the wall. In other parts masonry walling is measured by the rood of 36 square yards, or 24 cubic yards, the standard thickness being 2 feet; or by the rod of 272 feet super, as in brickwork, at a standard thickness of 18 inches or 2 feet.

In engineering, as distinct from architectural constructions, masonry is rarely valued otherwise than by the cubic yard for the roughest descriptions of work, and by the cubic foot for superior work.

The price in all cases varies with the quality and description of work, as 'coursed' or 'uncoursed,' in 'walling' or 'foundations.'

The superficial content of the surface-work is paid for separately by the square foot, yard, or rood of 36 square yards, including jointing or pointing, and such squaring to beds and joints as may be required, quoins, &c., of selected stones being often paid for at so much extra per foot run.

Superior work, such as squared masonry, whether in walling or dressings, is usually valued by the foot cube as block stone, merely scabbled or sawn to the required dimensions and set. The work upon it is taken separately by the foot super.

When different descriptions of masonry occur in a wall, such as rubble faced with ashlar, instead of cubing out the rubble and ashlar work separately—in which case the latter is valued by the cubic foot prepared and set, including all beds and joints, the facework being taken by the foot superficial as tooled, pointed, &c.—the whole may be taken as rubble masonry, and so much extra allowed per foot superficial for the superior facing, including all extra labour, dressing, and pointing.

When walls are built of rubble masonry, it is invariably cheaper to buy bricks at 30*s.* to 40*s.* per 1,000, and build them into such parts as jambs and arches, the labour upon which would be much less than in those shown on the face of the wall.

The block stone for the cut stonework in a building is ordinarily sold at the quarries, or delivered, by the cubic foot, or in large rough blocks by the ton, of from 13 to 17 cubic feet, according to the description of the stone, 1 inch being allowed each way for irregularities and waste.

QUANTITY OF STONE EQUIVALENT TO 1 TON IN WEIGHT.

SECTION VIII

PART II

MORTARS—CONCRETES—CEMENTS—PLASTERS

Revised and amplified by Alfred B. Searle
(Consulting Advisor on Cementitious Materials).

MORTARS.

Mortars are pasty substances which gradually harden on exposure; they are used for uniting stones or bricks in the construction of masonry or brickwork.

The chief kinds of mortar are:

Lime mortar, composed of lime and sand.

Trass mortar, composed of lime, sand, and trass or brick-dust, or of lime and trass without sand.

Cement mortar, composed of Portland cement (or other silicious cement) and sand.

Hydraulic mortar, composed of either hydraulic lime or cement, and sand, and characterised by its power of hardening under water.

Clay mortar, consisting of a mixture of fireclay and crushed firebricks, and used chiefly in the construction of furnaces, kilns, and other structures which have to be heated to high temperatures.

Lime Mortar.

The chief ingredients of ordinary lime mortar are lime and sand, but other materials, such as crushed bricks, ground stone or trass, and waste products such as ground slag, ashes, or coke, may, under suitable conditions, replace some of the sand. The tenacity of the mortar may be increased by the addition of hair or other fibrous material.

The best mortar for use in air * consists of a mixture of lime, sand, and brick-dust, but the latter is usually omitted on account of its cost.

Lime mortars made of fat or pure lime should not be used for roads, bridges, viaducts, waterworks, or any structure exposed to water, and some authorities maintain that even for churches, houses, and other buildings, it should not be used without the addition of trass or its equivalent, so as to prevent the flaking, crusts, and canker which are produced when too fat a lime is used.

Hydraulic lime mortar is composed of hydraulic lime and sand, the proportions varying from 3 to 6 measures for each measure of the lime (see *Lime Concrete*, p. 395). The chief use of this kind of mortar is for structures exposed to water, but unless the hydraulic lime is well selected, the structures may develop crusts and canker. Portland cement mortar is usually much superior to mortar made with hydraulic lime.

Trass Mortar.

Trass mortar is but little used in Great Britain, but has been used extensively abroad, and particularly in the East. The term 'trass mortar' is not confined to mortars containing true trass, but includes those containing similar materials, such as brick- or tile-dust, pozzolana, santorin earth, and other metamorphosed alumina silicates, which combine with free lime to form an indefinite compound having cementitious properties. The use of trass or similar material overcomes the disadvantages which accompany the use of fat-lime. The best proportions for trass mortars are shown in the table on p. 393. An excess of trass does no harm.

Cement Mortar.

Cement mortar consists of a mixture of sand and Portland cement, the usual proportions being 2 to 6 measures of sand to 1 of cement, according to the strength required. The best proportions for various purposes are shown in the table on p. 393. For structures exposed to

* Mortars for use under water are termed *hydraulic* mortars.

the air there should be more than twice as much sand as cement, but for completely waterproof structures the proportion of cement should not be less than half the sand used.

Lime is sometimes added to cement mortar to increase its plasticity and to make it easier to use. The addition of not more than 20 per cent. of hydrated lime slightly increases the strength of the concrete, but if the latter is exposed to water (inch rain), the free lime may be washed out, leaving a porous material which soon flakes and disintegrates when exposed to frost. These drawbacks can be avoided by adding trass instead of lime—a cement mortar composed of two measures of cement, one of trass and six measures of sand, being of wide application and easy to work.

All cement mortars are hydraulic—i.e. they harden readily under water.

Raw Materials for Mortars.

The *lime* should not be too 'fat' or pure, as such lime hardens chiefly by combination with carbon dioxide in the air, and then only externally.

Lean (i.e. less pure) lime * and hydraulic lime, on the contrary, harden in a manner similar to cement. The addition of trass or brick-dust to slaked lime has a similar effect on the manner in which the mortar hardens.

Hydraulic limes differ from the 'fat' or quick limes in consisting of an indefinite compound of lime and clay, which may be regarded as a crude Portland cement (p. 402), containing a large excess of free lime. The hydraulic limes owe their power of setting and hardening under water to this lime-clay compound, and consequently form a stronger brickwork or masonry than is produced by common mortar. Some hydraulic limes consist of a mixture of quicklime, true hydraulic lime, and inert or unburned material; for important work they should be tested and the proportions of these ingredients ascertained, as in hydraulic lime the proportion of cementitious matter present is more important than the percentage of lime.

Lias lime is hydraulic lime obtained from clayey limestones occurring in the Lias formations.

Quicklime should be slaked or hydrated before use; hydraulic lime should be bought in the form of a powder. Slaked lime should pass completely through a 60-mesh sieve, and should not leave more than 8 per cent. residue on a 100-mesh sieve. Hydrated or hydraulic lime should not leave more than 8 per cent. of residue on a 100-mesh sieve.

A hydraulic lime, when mixed with 30–50 per cent. of its weight of water and stored under water at 60° F., should harden sufficiently not to be indented with the finger-nail in about three days.

The *sand* used for mortars should consist of sharp (angular) grains of various sizes. Rounded grains do not interlock sufficiently to produce as strong a mortar.

Crystalline quartz sand is to be preferred to mica or felspar sand; the usual description 'good, clean, sharp sand' is much too wide. The grains of sand which are angular give the best results of tensile strength, those that are round give the highest compression strength. It is advisable to submit the sand to a microscopic examination to ascertain its suitability, as a considerable variation in the strength of mortar may occur, owing to the form and variety of the sand particles. From trials made with mortar composed of 1 of cement and 3 of sand a difference of strength varying from 171 lbs. to 313 lbs. per sq. in. was found, owing entirely to the difference in the sand; normal sand mixed in above proportions gave 256 lbs. per sq. in. in 28 days.

It is very important that the sand used for mortars and concrete should be free from clay and decomposed vegetable matter (*humus*). A simple test, devised by D. Abrams and O. Harder, consists in shaking the sand vigorously with a dilute solution of caustic soda, allowing the sand to settle and noting the colour of the overlying liquid. If it is dark-coloured, the sand is probably unsuitable for use: a pale yellow colour may be neglected.

The grading of the sand, i.e. the proportions of grains of different sizes, deserves far more attention than has yet been paid to it. By the use of a suitably graded sand, it is easy to reduce the proportion of the more expensive lime or cement by about 33 per cent. of that required for a less suitable sand. For most purposes the sand should contain about 30 per cent. of air-spaces or voids between the grains. The proportion of voids may be estimated by filling a measure with sand, and then pouring in water until the water is level with the top of the sand. The ratio of the volume of water, added to the volume of the sand, is that of the volume of the voids to that of the sand.

The *water* used in the preparation of mortar should be free from decaying substances; hence, peaty water should not be used. Apart from this, its source and character are of small importance. Brackish water, and even sea water, does little harm as regards the strength of the mortar, but may cause scum or efflorescence on the structure. If both are available, soft water is better than hard. For cement-sand mortar the average will be about 22 per cent. of the cement and sand by volume, or about 20 per cent. by weight, for trass-cements and mortar 8 to 10 per cent. by volume.

---

* Limes which produce less than twice their volume of slaked lime in the form of an apparently dry powder are termed 'lean' or 'poor' limes.

Proportions for Mortars.

Mortars are usually made largely by guess-work, but to secure the best results—which are often the cheapest, as a large saving can be effected by preventing a waste of lime—it is necessary to determine the best proportion of sand for the particular lime used.

For many purposes, the most suitable proportions are from 2 to 5 measures of sand to 1 measure each of lime and brick-dust, or trass, but the latter is usually omitted, and large quantities of mortar consist of 1 measure of lime to 3 measures of sharp sand. When ashes * or coke dust are used, one measure of these materials usually replaces an equal amount of sand. For the cheapest mortar, 1 part of lime and 4 parts of sand is used, but such a mortar is weaker than is desirable for general work.

According to J. A. van der Kloes, who has investigated the matter very thoroughly, the best proportions for mortars for various purposes are as shown in the following table :—

Number.	Lean Lime.	Fat Lime.	Lime-Putty.		Trass.	Portland Cement.	Trass or Pozzolana Cement.	Sand.
			Solid.	Fluid.				
A.—Waterproof Mortars for Work which is continually under Water.

XVIII.	—	—	—	—	—	—	1	$2\frac{1}{2}$–3

For 1 cu. yd. of cement mortar, the following quantities of sand and Portland cement will be required :—

Proportions.		Sand.	Cement.
Cement.	Sand.	Cub. ft.	Lbs.
1	0	—	2,800
1	1	18·8	1,695
1	2	24·9	1,120
1	3	28·7	860
1	4	30·3	682
1	5	31·4	565
1	6	32·2	483

* The use of ashes in mortar is a frequent cause of scum or efflorescence in brickwork.

0·87 cu. ft. of neat cement mortar will result from mixing 0·36 cu. ft. of water with 1 cu. ft. of loose cement.

1 cu. ft. of loose Portland cement will make about—

4·1 cu. ft. of concrete mixed		1 : 2 : 4
5·0	,, ,,	1 : 2½ : 5
5·8	,, ,,	1 : 3 : 6
7·5	,, ,,	1 : 4 : 8

1 cu. ft. of loose Portland cement neat as cement mortar will cover about 10·4 sq. ft., 1 in. thick.
1 cu. ft. of loose Portland cement to 1 sand will cover about 17 sq. ft. 1 in. thick.
1 cu. ft. of loose Portland cement to 2 sand will cover about 25 sq. ft. 1 in. thick.
1 cu. ft. of loose Portland cement to 3 sand will cover about 34 sq. ft. 1 in. thick.
1 cu. ft. of loose Portland cement to 2 sand will lay about 146 bricks with ⅜-in. joint, and 247 bricks with ¼-in. joint.
1 cu. ft. of loose Portland cement to 3 sand will lay about 212 bricks with ⅜-in. joint, and 317 bricks with ¼-in. joint.
1 yd. super. of pointing brickwork in neat cement requires about 8 lbs. of cement.

The proportion of water required varies with the nature of the lime and sand used. (See the par. on *water*, on p. 392.)

Mixing Mortars.

If a mortar is to answer its purpose satisfactorily, it is obvious that the various constituents must be mixed as uniformly and intimately as possible, for wherever sand or other powdery or gritty substances accumulate in the mortar, no hardening or adhesion will take place, and the mortar will be almost useless at such points.

Small quantities of mortar may be mixed by repeatedly turning over the materials with a shovel, and afterwards with a trowel, so as to mix them very thoroughly. As the labour is hard, and workmen are not always sufficiently conscientious, machine-made mortar is often more reliable than that mixed by hand. The most suitable machine for mixing mortar consists of an edge-runner or pan-mill of moderately light construction, in which the materials are treated for 20 to 30 minutes. Some builders introduce large pieces of material into such a mill, and grind them therein. This is not desirable. No pieces larger than ½ in. diameter should be introduced into a mortar mill, and if any materials more than $\frac{1}{16}$ in. diameter are present, the mixing must be prolonged until they have all been reduced to $\frac{1}{32}$ in. or less in diameter.

Choice of Mortar.

Mortar made with ordinary lime should not be exposed to water.

Mortar made with hydraulic lime should not be exposed to running water, unless the mortar also contains trass.

Cement-mortar is best where great strength is required a short time after completing the structure, but where a longer period of hardening is permissible, lime-trass mortar is cheaper and equally durable.

For the interior of kilns, furnaces, and flues, clay mortar should be used.

Coloured Mortars.

(L. G. Sabin.)

CONCRETES

Concretes are very coarse mortars, containing stones, gravel or ballast, sand, and a binding agent such as lime or cement. They are known by various names, according to the binding agent employed.

Lime concrete usually consists of a mixture of 1 part lime, 4 parts gravel, and 2 parts sand.

The best way of making lime concrete is by mixing together unslaked or hot, fresh-ground lime with sand and ballast, in the required proportions, on a stone, brick, or wooden floor, turning it over twice to dry, and then, as it is shovelled to a third heap, adding from the rose of a watering-can sufficient water only to slake the lime and make the ingredients cling together in a pasty mass, turning it over well as the water is added. Generally speaking, it will take about $\frac{3}{4}$ gallon to each cubic foot of ballast, but much will depend on the nature of the concrete and the dryness of the ballast employed.

Although frequently employed, fat or quick lime should not be used for lime concrete exposed to the weather, only hydraulic lime being suitable.

Beton is a French term, originally applied to lime concrete, but now used for any kind of concrete.

Cement concrete (more commonly known as *concrete* or *mass concrete*) is a mixture of stones, gravel or ballast, sand, and cement. Coke, clinker, and other materials are sometimes used to replace part of the stones, etc.

Breeze concrete consists of a mixture of 3 measures of small pieces of coke (preferably gas-works coke breeze), 1 of sand, and 1 of Portland cement. It is cheap, and nails can readily be driven into it. Its great disadvantage is that, in the event of a conflagration, it may take fire and increase the resulting damage instead of diminishing it.

Concrete made of ashes or clinker is sometimes, but erroneously, termed 'breeze concrete.'

Slag concrete is a mixture of crushed slag and Portland cement. It has been reported as having a greater compressive strength, less weight per cubic yard, and greater resistance to impact than concrete made with natural stone, but various failures which have occurred when slag concrete has been used have made many engineers unwilling to employ it. According to Dr. J. E. Stead, these failures were chiefly due to (1) using too little cement, and (2) the use of fine slag contaminated with ashes and other deleterious substances. In Dr. Stead's opinion, pieces of slag of less than $\frac{1}{2}$-in. diameter should not be employed in concrete. Fine slag, when moistened, is liable to evolve sulphuretted hydrogen, which has a very objectionable odour.

Reinforced concrete or *ferro-concrete* consists of a concrete structure, the strength of which is increased by the immersion of steel rods or wires in the concrete (see Section X, p. 435).

Raw Materials for Concrete.

All concretes consist essentially of a coarse aggregate, a fine aggregate, and a binding material or cement.

The *coarse aggregate* should consist of suitable stone, gravel or ballast, coke breeze, clinker, or other hard material of ample resistance to crushing, low porosity (absorbing less than 6 per cent. of its weight of water), and not liable to rapid disintegration by frost. The aggregate should be clean, and if necessary it should be washed before use. Except for the largest and roughest work, all the pieces of coarse aggregate should pass through a 2-in. ring.

The *fine aggregate* should consist of sharp, quartzose sand, similar to that used for mortar (p. 392). If trass is added, the concrete will be more resistant to water. Wet sand requires more cement than dry sand. The sand should be free from clay, and if necessary should be washed before use.

The *cement* may consist of hydraulic lime, Portland cement, or one of the cruder cements, such as *natural cement*, *Roman cement*, *Grappier cement*, *slag cement* (*iron Portland cement*), or various mixtures of Portland cement with sand, blast furnace slag (*Montan cement*), iron ore, etc.

Of these, Portland cement is the strongest and most reliable. It should conform to the Standard Specification (p. 404) For further information, see pp 402-406.

The *water* used for concrete should be the same as that for mortar (p. 392).

Proportions for Concrete.

To obtain the best results, the proportion of coarse aggregate (stones, gravel, etc.) should be such that the interstices or voids between its particles are wholly filled with sand, the interstices or voids in the sand being then filled with cement; additional cement, sufficient to cover all the particles of aggregate with an adhesive coating, should also be present.

As the determination of the voids is often troublesome, many engineers adopt definite proportions of coarse and fine aggregate and cement. For reinforced concrete work where very good concrete is required, the proportions are usually 1 of Portland cement to 2 of sand to 4 of coarse material. For a medium quality concrete, such as is used for foundations, walls, arches, ordinary floors and stairs, the proportions should be 1 : 2½ : 5. For heavy walls, retaining walls, piers, and abutments which are subjected to considerable strain, the concrete can, however, be poorer, 1 : 3 : 6. Wherever concrete is employed in large masses, and is subjected to simple compression of small intensity, or is used for a backing for brickwork or masonry, or for covering the site of a building to prevent the damp rising from the soil, a still poorer concrete can be used of 1 : 4 : 8. In such work and in foundations large stones (commonly called 'plums') can often be placed by hand in the mass some little distance apart so as to allow them to be surrounded by the concrete; these economise considerably, without greatly reducing the strength of the mass.

For concrete to be used under water, a mixture corresponding to a cement-trass mortar is preferable (see the table on p. 393).

The following table shows the relative weights required to produce the proportions mentioned in the first column; from it the cost of materials per cu. yd. of concrete for various mixtures can be ascertained.

MATERIALS FOR 1 CU. YD. OF CONCRETE.

Based on loose cement weighing 90 lbs. per cu. ft., with an average specific gravity of 3·12 and a cu. ft. of loose, moist, coarse sand weighing 89 lbs. when dried.

Proportions.	Kind of Coarse Material.	Lbs. Portland Cement in 1 cu. yd.	Sand cu. yds. in 1 cu. yd.	Coarse Material, cu. yds. in 1 cu. yd.
1 : 1½ : 3	Shingle (40 per cent. voids)	666	·41	·82
Do.	Broken stone (45 per cent. voids)	697	·43	·86
1 : 1⅔ : 3½	Shingle	610	·42	·84
Do.	Broken stone	640	·44	·88
1 : 2 : 4	Shingle	520	·43	·86
Do.	Broken stone	548	·45	·90
1 : 2½ : 5	Shingle	430	·44	·88
Do.	Broken stone	450	·46	·92
1 : 3 : 6	Shingle	364	·45	·90
Do	Broken stone	383	·47	·94
1 : 4 : 8	Shingle	280	·46	·92
Do.	Broken stone	294	·48	·97

This table does not apply to concrete made with a single aggregate, such as Thames ballast, to which no sand is added, but where proper scientifically proportioned concrete is employed, as should always be the case, the values given in the table are accurate and correspond with experience.

The proportion of water used in mixing concrete is much more important than is commonly realised, as it has a great influence on the strength of the concrete. According to D. A. Abrams,

$$\text{Compressive strength of concrete in lbs. per sq. in.} = \frac{14{,}000}{7x},$$

where x is the ratio (by volume) of water : cement. If this is the case, a comparatively small excess of water must have a very harmful effect. The American practice of using a very wet mixture is not to be recommended where great strength is required.

In measuring out the materials, the fact must not be overlooked that about 34 cu. ft. of stone, sand, and cement will be required for each cu. yd. of concrete, as the sand and cement occupy the interstices between the pieces of coarse aggregate.

Mixing Concrete.

Concrete may be mixed by hand, as described on p. 394, but large quantities are preferably mixed by machinery. Various types of mixing machines have proved satisfactory, but the ones most largely used consist of a cylinder, fitted with baffle plates internally and mounted on trunnions so as to be revolved rapidly.

WORKING CAPACITIES OF STEAM-DRIVEN MIXERS.

(Ransome Machinery Company, 1920, Ltd.)

Standard size of mixer	00	0	1	2	3	4	5
Nominal batch capacity	2 ft.	¼ yard	½ yard	¾ yard	1 yard	1½ yard	2 yard
Capacity of gauging hopper	cu. ft. 3	cu. ft. 7·25	cu. ft. 16	cu. ft. 24	cu. ft. 36	cu. ft. 56	cu. ft. 80
Approximate output per batch of mixed concrete using broken stone	cu. ft. 2	cu. ft. 5	cu. ft. 11	cu. ft. 16	cu. ft. 24	cu. ft. 38	cu. ft. 54
Approximate output per batch of mixed concrete using ballast or gravel	cu. ft. 2·25	cu. ft. 5·5	cu. ft. 12	cu. ft. 18	cu. ft. 27	cu. ft. 42	cu. ft. 60
Average guaranteed output per day (10 hrs.) using broken stone	cu. yds. 22	cu. yds. 55	cu. yds. 118	cu. yds. 180	cu. yds. 270	cu. yds. 415	cu. yds. 592
Average guaranteed output per day (10 hrs.), using ballast or gravel	cu. yds. 25	cu. yds. 60	cu. yds. 133	cu. yds. 200	cu. yds. 300	cu. yds. 470	cu. yds. 660
Maximum output which has been obtained per day (10 hrs.)	cu. yds. 50	cu. yds. 120	cu. yds. 266	cu. yds. 400	cu. yds. 600	cu. yds. 940	cu. yds. 1,320
Brake horse-power required	2	3	6	10	15	20	35

NOTE.—In the production of concrete it is impossible to guarantee definitely the exact amount of mixed material which will be produced from a given quantity of aggregate, owing to the varied nature and size of the stone used, but the above figures, based on actual results, may be taken as approximately correct.

The mixing should be as rapid as possible, consistent with thoroughness, as the concrete should be placed in position before it has begun to set.

Remixed concrete should never be used.

For descriptions of mechanical mixers and further information on mixing concrete, see 'Cement, Concrete, and Bricks,' by A. B. Searle (Constable).

Placing Concrete.

In ordinary foundations, the concrete should be deposited in horizontal layers, not more than a foot thick, and care should be taken to cover any joints in one layer by the succeeding one, as the joint between two days' work is always a weak part; moreover, the last-laid layer should be well wetted, to ensure a proper connection with the next.

The chief mistake made in placing mass concrete is in failing to secure sufficient adhesion to the previously placed material. In reinforced concrete there is often a danger of incomplete filling, particularly around the more complex portions of the reinforcement; this may be minimised by the use of a wetter mixture or by efficient damping or vibration. If the latter is effected mechanically, care must be taken not to continue it so long that the setting of the concrete is disturbed.

Fine concrete or cement mortar may be sprayed on to the surface to be covered by means of a *cement gun* operated by compressed air (see p. 400). This method is particularly effective for 'plastering' with cement mortar, or in the construction of walls about 2 ins. thick on a basis of expanded metal or wire netting.

As the right placing of concrete is of great importance, it may be desirable to consult one or more textbooks on the subject.

Volume of Concrete.

The volume of a mass of concrete is much less than that of the separate ingredients, owing to the voids or interstices between the particles of coarse aggregate being occupied, in the concrete, by the sand and cement. Roughly,

Mixture.	Volume of coarse aggregate.	Volume of concrete.
1 : 2 : 4	1 cu. yd.	1·07 cu. yd.
1 : 2½ : 5	1 cu. yd.	1·02 cu. yd.
1 : 2 : 8	1 cu. yd.	1 cu. yd.

1 cu. ft. of loose Portland cement will make about :—

4 cu. ft. of 1 : 2 : 4 concrete.	6 cu. ft. of 1 : 3 : 6 concrete.
5 cu. ft. of 1 : 2½ : 5 „	7½ cu. ft. of 1 : 4 : 8 „

For the quantities of materials required for concrete floors, see pp. 393, 394.

Weight of Concrete.

The weight of 1 cu. ft. of concrete varies with the proportion and nature of the aggregate used.

The average weight of 1 : 2 : 4 concrete, using sand as fine aggregate and one of the following coarse aggregates, is: coke breeze, 100 lbs. per cu. ft.; clinker, 110 lbs. per cu. ft.; sandstone, 120 lbs. per cu. ft.; bricks, 125 lbs. per cu. ft.; limestone, 135 lbs. per cu. ft.; shingle, 145 lbs. per cu. ft.; granite, 145–150 lbs. per cu. ft.

Strength of Concrete.

A large excess of water and too little water are both adverse to the production of strong concrete.

Concrete containing too much cement may be weaker than that containing less cement.

Badly mixed concrete is weak in some parts and strong in others.

The addition of 10 per cent. calcium chloride to the mixing water increases the strength of mass concrete, but cannot be used for reinforced concrete as it corrodes the reinforcement.

The compressive strength of most concretes, as commercially made, can be increased 25 to 100 per cent. or more by employing rigid inspection which will ensure proper methods of fabrication of the materials.

According to H. C. Johnson :—

For equal working consistency and equal cement, gravel concrete is as strong as stone concrete.

Gravel passing same screens as stone always has less voids than the stone.

Fine sand concrete has smaller weight per cubic foot than coarse sand concrete.

Fine sand plus large aggregate (without cement) gives *smaller* volume than coarse. Fine sand plus large aggregate (with cement) gives *larger* volume than coarse.

Fine sand concrete is easier worked than coarse sand concrete for equal amounts of sand.

The finer the aggregate the more deleterious material and air it carries with it into the concrete.

The finer the sand the less should be used.

30–40 per cent. higher strengths are obtained with 3·16 in. cubes than with 6 in. cubes.

Small cubes are more uncertain and inconsistent in the strength values than larger cubes.

The requirements of the London County Council and the Specification drawn up by a Joint Committee of the Royal Institute of British Architects, District Surveyors' Association, Institute of Builders, Institute of Municipal and County Engineers, War Office, Admiralty, London County Council, and the Concerte Institute, call for a crushing strength of 1,800 lbs. per sq. in. at 28 days and 2,400 lbs. per sq. in. at 90 days, for a 1 : 2 : 4 mixture.

The figures 1,400 at 28 days and 2,000 at 90 days more nearly represent the results obtained under ordinary working conditions, with an aggregate like Thames ballast.

The strength of concrete continues to increase long after it has been made, and is by no means at its maximum after 90 days.

Weather conditions have a marked effect on concrete work. Heat hastens the hardening process; cold delays it. The effect of cold becomes noticeable when temperatures fall below 50° F., and becomes more marked with lower temperatures. As a rule, concrete does not show any serious effects from having once been frozen if, after it thaws out, it is not again frozen until early hardening is complete. It is better, however, to protect the concrete from freezing for from forty-eight hours to four or five days, depending upon the degree of the cold, rather than to expose it to the possibility of freezing. Warmth and moisture are necessary to the proper hardening of concrete.

It is especially important to keep concrete thoroughly saturated with water for at least a week, as if it is allowed to dry too soon, it never develops its full strength.

Effect of Sea-water on Concrete.

The effect of sea-water on concrete depends on the permeability of the latter, dense, waterproof concrete being largely resistant to sea-water, whilst porous concrete corrodes readily. For exposure to sea-water, the concrete should contain a considerable proportion of trass, or equivalent, a suitable mixture consisting of 1 measure of trass, 1 of Portland cement, and 2½ to 3 measures of aggregate. The aggregate should consist of coarse and moderately fine particles, in such proportions as to produce a concrete of maximum impermeability.

Condensation on Concrete.

Concrete is subject to condensation when the air is wet or humid, and a non-porous concrete is subject to more condensation than a porous concrete. A weak concrete of broken brick aggregate will have proportionately the same porosity as the porous brick itself.

Interior plastering will prevent condensation on any sort of concrete. A good method is to cover the interior of the concrete walls with ordinary plasterer's lime and sand mortar (about 3 of sand to 1 of lime), lightly keyed in the usual manner to receive the final setting coat. This coat must be left until strong pressure from the thumb makes no impression. It may be necessary to leave it for several days, according to the weather. The finishing coat of lime, putty, sand and plaster of Paris may then be applied with safety. Immediately before this latter coat sets, it should be finished with a soft hair brush, which produces a granular surface, a further method of absorbing moisture.

The best and most easily obtainable finishing coat is the following:

Three parts of lime putty or chalk lime; 6 parts of washed sand; 1 part of plaster of Paris. It gives a good finish, sets well, and works quickly.

Instead of making dense concrete for walls, it is much cheaper and more hygienic to use a very porous concrete, and to render it with a cement waterproofed exterior coating, for the fiercest driving rain cannot penetrate a $\frac{3}{4}$-in. pudlced cement rendering. Porous concrete, like all porous materials, has also the quality of retaining the heat engendered in the room, thus giving a warmer dwelling. Therefore porous concrete has the dual advantage of assisting the absorption of condensation and of conserving heat. (*J. H. Kerner-Greenwood.*)

Preventing Scaling and Cracking of Concrete.

The best method of preventing *scaling* is to keep the concrete thoroughly wet for a week or more after it has been placed, the surface being protected with wet cloths, sawdust, or other porous material.

Cracking may be prevented in the same manner, except in those cases where insufficient allowance has been made for stresses due to load or to expansion.

To Stop Leakage through Concrete.

Leakage or seepage through concrete is best stopped by cleaning the surface thoroughly, making good any cracks or fissures, and then covering the surface with a waterproof cement mortar. (See *To Waterproof Concrete*, below.)

The application of several coats of a solution of zinc sulphate, or of water-glass (silicate of soda), is cheaper, but seldom so effective.

Rust Prevention in Reinforced Concrete.

Various methods have been proposed for preventing the reinforcement from rusting. Under ordinary circumstances, no special precautions are necessary, and if the corrosion is due to electric currents no application of chemicals can be satisfactory.

The use of galvanised reinforcement has been stated to prevent rusting, and also to secure greater adhesion between the metal and the concrete.

Treatment of Dusty Concrete Floors.

Various hardening solutions are sold for preventing concrete floors from being dusty, and to give a better wearing surface. The composition of most of these solutions is a trade secret

Two excellent hardening solutions are the following:—

Mix 1 part silicate of soda to 4 or 5 parts water. Brush or sprinkle the floor well with this solution, and allow to dry. Then, after 4 hours and within 24 hours, wash clean with clean water. Repeat the treatment three times.

(2) The following solution has been recommended by *Concrete*:—

To 10 gallons of cold water add 1 fluid ounce of sulphuric acid. Heat the liquid to boiling point and stir in 25 lbs. of sulphate of alumina. Let the solution cool and strain. Sweep and thoroughly wash the concrete surface. After drying, lay on the hardener in four applications of varying strength, ranging from 30 per cent. solution and 70 per cent. water, up to 100 per cent. solution. The above quantity suffices for the complete treatment of an area of from 50 square yards to 100 square yards, depending upon the porosity of the surface treated.

To Waterproof Concrete.

Concrete may be made waterproof by taking care to use such proportions of the various ingredients as will produce a dense and impermeable material.

As this is not always practicable, it is often preferable to add a waterproofing agent prior to mixing the various ingredients. The chief of these additions are:

(1) *Oil* or a solution of paraffin wax in benzoline or other cheap volatile solvent.

(2) *Insoluble soap* made by impregnating the concrete with a solution of alum, and afterwards with a solution of soap. Suitable proportions are:—

One part of cement, 2 parts of sand, ¾ lb. of dry powdered alum to each cubic foot of sand. These are mixed and dried, and to them is added water in which has been dissolved ¾ lb. soap to each gallon. This, it is said, is nearly as strong as ordinary cement, and is quite impervious to water, and does not effloresce. For a wash, a mixture of 1 lb. of lye and 2 lbs. of alum in 2 gallons of water is often used.

(3) *Water-glass* (silicate of soda) applied in the form of a wash or spray, several applications being necessary at suitable intervals.

(4) *Secret mixtures* sold under various trade names, such as Prufitol, Bareau, Prufit, Pudlo, etc.

Building Products Ltd. (51 Columbia House, 44/46 King's Road, Chelsea, S.W. 3) supply a preparation called PRUFITOL for applying by brush or spraying machine to porous brick, stone, cement, or stucco work, which will keep out driving rains.

The integral system of incorporating a waterproofing agent with the cement and aggregate may be performed by mixing BAREAU cement waterproofing powder with the dry cement, or PRUFIT cement waterproofing paste with the gauging water.

These specialities are supplied by *Building Products Ltd.* (51 Columbia House, 44/46 King's Road, Chelsea, S.W. 3), who specialise in structural waterproofing problems and provide specifications for particular work.

'CEMENT GUN' MACHINE FOR APPLICATION OF HYDRATED MATERIALS.

(Supplied by Fleming & Co., 31 Robertson Street, Glasgow.)

In this machine, sand and cement, previously mixed dry, are placed in a hopper, from which the mixture is automatically fed through an air-locking device and hose to a nozzle, where water is automatically added, and by the aid of compressed air the 'Gunite' (as the mixture is called) is sprayed in a perfectly hydrated state on the surface to be coated.

The propelment of the material by the pneumatic pressure against the surface to be covered, ensures a very dense, hard, and durable mortar. It also means the elimination of heavy and expensive forms, for the material builds up against the backing to a considerable thickness without losing its high quality.

Tests showed that the modulus of elasticity of 'Gunite' was at the end of ninety days, on one part cement to three parts sand mixture, 4,705,000; on one part cement to two-and-a-half parts sand mixture, 4,760,000.

On prisms made of mixtures consisting of one part cement and three parts sand, at the end of ninety days an average ultimate compressive strength of 4,000 lbs. per sq. in. was obtained; on prisms consisting of mixtures containing one part cement to two-and-a-half sand, 4,600 lbs. per sq. in.

It was found that the adhesion between new and old surfaces was absolutely permanent.

'Gunite' has a very high resistance to salt water action.

CONCRETE BLOCKS, TILES, AND OTHER ARTICLES.

In addition to masses of concrete moulded *in situ*, large quantities of blocks, tiles, garden vases, fencing posts, troughs, and other articles made of concrete or of cement-sand mortar (p. 391) are in regular use, and afford clear proof of the manifold uses of this material.*

For *concrete floors*, see p. 750.

ASBESTOS BUILDING SHEETS.

The use of sheets composed of Portland cement, asbestos, and a neutral filler, has greatly increased during recent years. These sheets require costly plant for their production, so that it is usually necessary to buy them ready-made. They are usually sold under various trade names.

Plain sheets are used for walls and roofs; corrugated sheets are largely used in place of those made of corrugated iron. Small sheets are used instead of roofing tiles (see p. 335).

* For further details see *Concrete and Constructional Engineering*, *Everyday Uses of Portland Cement*, and various textbooks on concrete.

Ægis' Asbestos-Cement Building Sheets.

8′ × 4′ or 4′ × 4′

These sheets (*Turner Brothers Asbestos Co., Ltd., Rochdale* are readily worked and quickly fixed with ordinary carpenters' tools.

Ceilings.—For ceilings, sheets $\frac{5}{16}$ in. or $\frac{3}{16}$ in. thick are most suitable, and are nailed to ceiling joists with 1¼-in. galvanised or copper nails at not less than ½ in. from edge of sheets, and about 6-in. centres, care being taken that edges butt closely and nail heads are flush.

In forming ceilings, 4-ft. by 4-ft. sheets are recommended. These are quickly and easily handled by the erectors, and the ceilings may be subdivided into panels, the joints being covered with a moulded wood or fillet strip, the result giving a highly decorative effect.

Partitions.—These may be formed with sheets $\frac{5}{16}$ in. to ½ in. thick, nailed as before described to timber studding, spaced at 1 ft. 4 ins. or 2 ft. centres. Between the standards, dwangs or struts should be placed to support the ends of the sheets. The joints may be filled before painting, and the whole surface rubbed down in the usual way, or as an alternative covered with moulded wood or fillet strips.

For 'Fibrent' Asbestos Cement Building Sheets, see p. 336.

Bell's Hurcan Building Slabs.

'Hurcan' slabs (*Bell's United Asbestos Co., Ltd.*) are composed of cement concrete of the highest quality faced with asbestos cement. The slab is so well finished that for interior work no plastering is required, and owing to the asbestos facing, decoration can be applied directly after priming, either distemper, paint, or wallpaper.

The exterior effect of the slabs is that of ashlar stonework.

The slabs are 3 ins. thick (2 ins. in the frog). The standard sizes are 9 ins. up to 24 ins. long (increasing by 3 ins. units) by 12 ins. deep.

Special blocks are made for the external corners of the building, and end-faced slabs for reveals of windows and doors. Partition slabs are faced on both sides and 3 ins. thick.

The weight of the material is approximately 26 to 30 lbs. per square foot, or about 9 yds. super (single thickness) per ton.

The cost is slightly less than that of bricks, and considerable economy is effected in labour, mortar, and entire elimination of plastering.

For information on Bell's *Poilite* sheets, see p. 335.

CEMENTS.

Cements are materials used for uniting other materials or articles so that they adhere permanently. There are many kinds of cements, but the more important ones may be grouped as follows:—

(1) *Mastic cements*, in which the chief ingredient is red lead with a gum or boiled oil, and sand or other inert material.

(2) *Fish-glue cements*, or liquid glues, made by treating fish bones with acetic acid. *Seccotine* is of this character.

(3) *Casein cements.*

(4) *Bituminous cements*, in which the chief ingredient is tar, pitch, or bitumen (see *Plastic cements*.

(5) *Water-glass cements*, which consist chiefly of an inert material mixed with water-glass (syrupy silicate of soda) (see Section XXXIX).

(6) *Calcareous silicate cements*, such as hydraulic lime, Roman cement and the various natural cements, and Portland cement. *Hydraulic limes* are described on p. 392. *Roman cement* is a brown, quick-setting cement, made by calcining and grinding the septaria or calcareous clay-stones found in London clay. It is one of the natural cements.

Natural cements (so-called) are made by heating natural mixtures of clay and limestone to redness, so as to effect a combination between the lime and clay similar to that in Portland cement. Such natural cements are comparable to a mixture of Portland cement with either an excess of lime or clay, as the case may be. Their composition is irregular and uncertain, so that they are inferior to Portland cement for all work of importance. They can be greatly improved by adjusting their composition by the addition of limestone or clay, as may be required, and heating until the mixture is clinkered. Such adjustment greatly increases the cost of production, but produces a Portland cement. *Portland cement* is described on pp. 402-406.

(7) *Gypsum cements*, such as plaster of Paris, Keene's cement, Parian cement (see *Plasters*,' p. 406).

(8) *Oxychloride cements*, of which the best known is Sorel cement, composed of dense magnesia and syrupy magnesia chloride (see Section XXXIX).

(9) *Refractory cements*, which are specially resistant to heat, and are therefore used in the construction and repair of furnaces, etc. (see pp. 429, 431, and Section XXXIX).

(9) *Miscellaneous cements* are described in Section XXXIX.

Portland Cement.

(Partly contributed by William Alden Brown, F.G.S., A.M.I.Mech.E., Assoc.A.M.Soc.C.E., Author of 'The Portland Cement Industry.')

Portland cement is usually made from a mixture of chalk, or limestone, and clay ground together in a wet state to an extreme degree of fineness, and subsequently dried, calcined and ground to the fineness of flour. Pats or briquettes made from it should, when broken, exhibit a bluish grey colour in the fracture. A buff or 'foxy' colour on the surface may be indicative of insufficient calcination or too low a proportion of lime in the composition of the cement; but too much importance must not be attached to colour alone, as a brown stain may be caused by the use of alkaline water for gauging or immersing the briquettes. The best brands of English Portland cement are now ground to such a fineness that the old-fashioned plan of shooting the cement into shallow bins or on a dry floor and turning it over at frequent intervals is not only unnecessary, but, when a cement is already sound and fit for use (as shown by such tests as the boiling or Le Chatelier), is positively detrimental. The addition of a very small percentage of gypsum to the cement during the grinding process for the purpose of retarding the setting time was formerly prohibited by many of the leading British engineers, but is now sanctioned. Gypsum increases the strength at three and seven days.

Portland cement may be obtained quick or slow setting. If there are no special reasons which make quick setting desirable, it is advisable to employ a cement which requires at least two hours to pass from the pasty state into the hard, solid one, as quick-setting cements require exceptional care and skill in gauging: otherwise they * begin to set and to spoil before they have been placed in their proper position in the structure.

Hydration has the same effect, and is not open to the objections that have been raised by some engineers to the use of gypsum. Cement must not be judged solely by tensile tests at the customary seven days, because the rapidity with which its strength develops depends largely on the percentage of lime in its composition and partly upon the presence or absence of gypsum. A cement containing a high percentage of lime (63 or 64 per cent.) develops its maximum strength rapidly, whilst one containing a lower percentage (60 to 62 per cent.) develops it more gradually. The former proportions are generally favoured by Continental makers, but British engineers have for the most part prohibited a larger proportion of lime than 62 per cent.

Temperature has a very great effect upon the setting time of cement. A sample tested in a temperature of 61° Fahr. and gauged with water at the same temperature took six hours to set hard. The same sample gauged in a temperature of 90° Fahr. and gauged with water of equal temperature set hard in one hour fifty minutes. This is a point which is often lost sight of.

Testing Portland Cement.

The tests usually applied relate to its

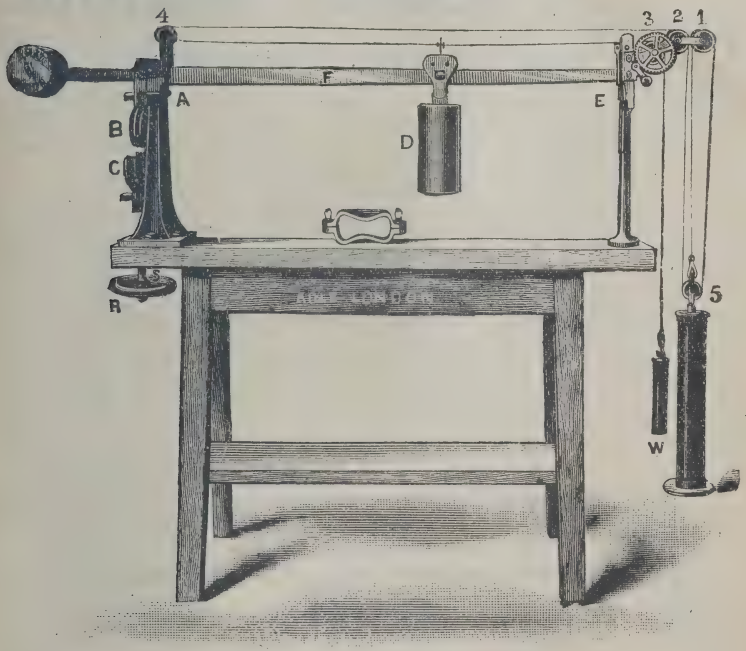
Chemical composition.
Specific gravity.
Fineness.
Tensile strength. (Neat cement.)
Tensile strength. (Cement and sand.)
Time of setting.
Soundness.

Chemical Composition.—This test is for the detection of adulterants, or to determine whether certain constituents are present in amounts exceeding that believed to be safe.

Specific Gravity.—This test is designed to detect under-burning and adulteration, and should only be used in connection with the chemical analysis; low specific gravity is often caused by 'ageing' of the cement, so that to reject a cement because of a low specific gravity may be to reject it because it has been well seasoned.

Fineness.—The fineness of the cement is a measure of its cementing value, and a fine cement will be much stronger when mixed into a mortar, or it can be mixed with a larger proportion of sand than a coarse one, and yet attain the same strength.

Tensile Strength (Neat Cement).—The test is to obtain a measure of the cohesive strengths of the particles of cement lying in the least section of the adjacent particles.



A neat briquette rupture is practically a plane section.

---

* The composition of Portland cements is highly complex. Some further indications of it are given in 'Cement, Concrete, and Bricks,' by A. B. Searle (Constable & Co., Ltd., London).

PATRICK ADIE

(Formerly BROADWAY WORKS),

45 HORSEFERRY ROAD, WESTMINSTER, S.W.1.

F. 403

Tensile Strength (Cement and Sand).—The test is to obtain a measure of the cohesive strength of the particles of the cement to the sand grains, and by shearing of the cement between overlapping grains of the aggregate.

A cement and sand briquette rupture is an irregular surface due to the projection of the sand particles, so that the actual area over which the rupture takes place is much in excess of the cross section.

Time of Setting.—The test is usually made to determine the fitness of the cement for a given piece of work.

Soundness.—The object of this test is to develop these qualities which tend to destroy the strength and durability of a cement, and is therefore the most important quality, for although a sample may pass all tests satisfactorily, if it fail in the soundness test it is worthless as a material for construction.

Failure is revealed by cracking, checking, swelling, or disintegration, or all of these phenomena.

A cement which remains perfectly sound is said to have a constant volume.

When gauging briquettes for testing purposes care should be taken to weigh out the proportions of cement and water accurately. The metric system is the most convenient for this. For the usual briquette of one inch breaking section 200 grammes of cement is a suitable quantity. The percentage of water materially affects the results obtained, higher results at the shorter dates accompanying lower proportions of water. About 18 to 20 per cent. of water (i.e. 36 to 40 cubic centimetres of water to 200 grammes of cement) is the usual practice, but a skilful gauger will often use even less than this and get proportionately higher results. Indeed, the skill of the gauger is unfortunately a most important factor, and no mechanical means have yet been successfully devised to eliminate this.

Cement Testing Machines.

Tension tests of cement briquettes are generally made on special testing machines of various types, single and compound levers being used. The application of the load at a steady and definite rate is in some cases accomplished by running water or fine shot through a controllable opening into a vessel hanging from the end of the lever; in other cases a travelling poise is caused to move along a graduated lever at a steady speed.

A single-lever testing machine made by Mr. Adie, with a regulated travelling poise D, is shown in fig. 697. The briquette is placed in the clips B, C, and the hand-wheel R serves to tighten the screw attached to the lower clip C, so as to raise the lever F into a position of balance between the stops on the standard E. The poise D may be moved along the lever F, by means of the handle at the end of the beam. For loading at a uniform rate the traverse of the poise is accomplished by the pull of a suspended weight W, regulated by a dashpot cylinder below the pulley 5; the rate of traverse is regulated by adjusting a cock in the piston of the dashpot.

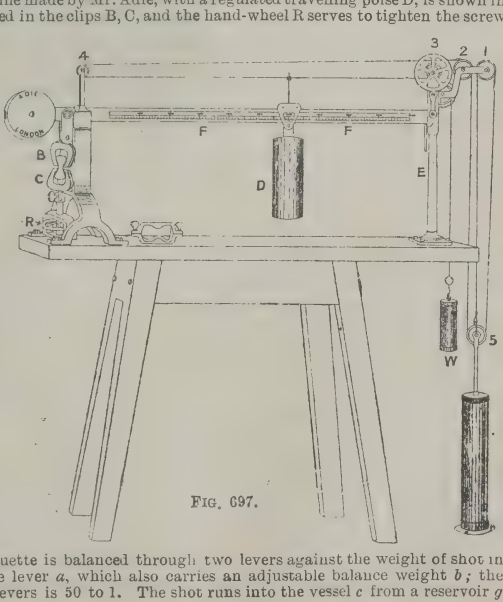

Fig. 697.

Fig. 698 shows the form of another of Mr. Adie's cement-testing machines, designed by Dr. Michaelis. This machine, which is of the compound-lever type and is loaded by shot, may be taken as typical of German practice. The briquette *i* is held between clips *d* and *e*, the lower one of which is attached to a straining screw turned by the hand-wheel *f*. The pull on the briquette is balanced through two levers against the weight of shot in the vessel *c* at the end of the lever *a*, which also carries an adjustable balance weight *b*; the combined leverage of the two levers is 50 to 1. The shot runs into the vessel *c* from a reservoir *g*

through a channel, which is regulated at *o* for any desired rate of loading by a lever *n*. The breaking of the briquette and consequent fall of the lever automatically shuts off the supply of shot, and 50 times the weight of shot in *c* gives the breaking load, this quantity being recorded by a spring balance at *l*.

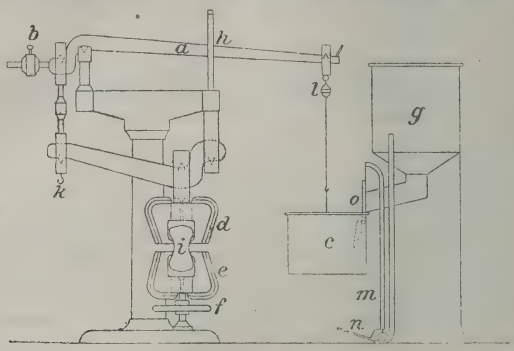

FIG. 698.

BRITISH STANDARD SPECIFICATION FOR PORTLAND CEMENT.*

(No. 12—1920.) (*Abstract.*)

1. The cement shall be manufactured by intimately mixing together calcareous and argillaceous materials, burning them at a clinkering temperature and grinding the resulting clinker, so as to produce a cement capable of complying with the specification.

No addition of any material shall be made after burning other than calcium sulphate, or water, or both, and then only if desired by the vendor and not prohibited in writing by the purchaser.

7. The sample or samples shall be tested for :—(*a*) fineness; (*b*) chemical composition; (*c*) tensile strength (neat cement); (*d*) tensile strength (cement and sand); (*e*) setting time; (*f*) soundness; and before any sample is submitted to tests (*c*), (*d*), and (*f*), it shall be spread out for a depth of 3 ins. for 24 hours in a temperature of from 58 to 64 degrees Fahrenheit.

8. The cement shall comply with the following conditions of fineness—100 grammes (or say 4 ozs.) of cement shall be continuously sifted for a period of 15 minutes on each of the undermentioned sieves and in the order of succession given below, with the following results :—

(1) The residue on a sieve 180 × 180 = 32,400 meshes per sq. in., shall not exceed 14 per cent.

(2) The residue on a sieve 76 × 76 = 5,776 meshes per sq. in., shall not exceed 1 per cent.

The sieves shall be prepared from wire-cloth, and the diameter of the wire for the 32,400 mesh shall be ·0018 in., and for the 5,776 mesh, ·0044 in. The wire-cloth shall be woven (not twilled), the cloth being carefully mounted on the frames without distortion.

9. The cement shall comply with the following conditions as to its chemical composition. The proportion of lime, after deduction of the proportion necessary to combine with the sulphuric anhydride present, to silica and alumina, when calculated (in chemical equivalents) by the formula $\frac{CaO}{SiO_2 + Al_2O_3}$, shall be not greater than 2·85 nor less than 2·0. The percentage of insoluble residue shall not exceed 1·5 per cent.; that of magnesia shall not exceed 3 per cent.; and the total sulphur content calculated as sulphuric anhydride (SO_3) shall not exceed 2·75 per cent. The total loss on ignition shall not exceed 3 per cent.

10. The breaking strength of neat cement shall be ascertained from briquettes of the specified shape. The briquettes shall be prepared in the following manner :—

The cement shall be mixed with such a proportion of water that the mixture shall be plastic when filled into the moulds used for forming the briquettes. The cement, gauged as stated shall be filled into moulds of the form required to produce briquettes of the specified shape each mould resting upon a non-porous plate. In filling the moulds the operator's hands and the

* By permission of the British Engineering Standards Association.

blade of the ordinary gauging trowel shall alone be used. The trowel shall weigh about 7½ ozs. No ramming or hammering in any form will be permitted, nor shall any other instrument or apparatus other than the trowel before described be employed for this operation. The moulds after being filled may be shaken to the extent necessary for expelling the air. Clean appliances shall be used for gauging, and the temperature of the water, and that of the test room at the time the above operations are being performed, shall be from 58 to 64 degrees Fahrenheit. The briquettes shall be kept in a damp atmosphere for 24 hours after gauging, when they shall be removed from the moulds and immediately submerged in clean fresh water and left there until taken out for breaking. The water in which they are submerged shall be renewed every seven days and shall be maintained at a temperature of between 58 and 64 degrees Fahrenheit. After they have been so taken out and until they are broken the briquettes shall not be allowed to become dry.

The briquettes shall be tested for breaking strength at 7 and 28 days respectively after gauging, six briquettes for each period. The breaking strength shall be the average tensile breaking strength of the six briquettes for each period. The briquettes to be tested shall be held in strong metal jaws of the specified shape, and the load shall be steadily and uniformly applied, starting from zero, and increased at the rate of 100 lbs. per sq. in. of section in 12 seconds.

The breaking strength of the briquettes at 7 days after gauging shall be not less than 450 lbs. per sq. in. of section.

The breaking strength of the briquettes at 28 days after gauging shall show an increase on the breaking strength at 7 days, and shall be not less than the number of lbs. per sq. in. of section arrived at from the following formula :—

$$\text{Breaking strength at 7 days} + \frac{40{,}000 \text{ lbs.}}{\text{Breaking strength at 7 days.}}.$$

11. The breaking strength of cement and sand shall be ascertained from briquettes of the specified shape. The briquettes shall be prepared in the following manner :—

A mixture of cement and sand in the proportion of one part by weight of cement to three parts by weight of the standard sand hereafter specified, shall be gauged with sufficient water to wet the whole mass throughout without any excess of water being present. The mixture thus gauged shall be evenly distributed in moulds of the form required to produce briquettes of the specified shape, each mould resting upon a non-porous plate. After filling a mould a small heap of the mixture shall be placed upon that in the mould and patted down with a standard spatula until the mixture is level with the top of the mould. This last operation shall be repeated a second time and the mixture patted down until water appears on the surface ; the flat only of the standard spatula is to be used and no other instrument or apparatus is to be employed for this operation. The mould after being filled may be shaken to the extent necessary for expelling the air. No ramming or hammering in any form will be permitted during the preparation of the briquettes, which shall then be finished off in the moulds by smoothing the surface with the blade of a trowel. Clean appliances shall be employed for gauging, and the temperature of the water and that of the test room at the time the above operations are performed shall be from 58 to 64 degrees Fahrenheit. The briquettes shall be kept in a damp atmosphere for 24 hours after gauging, when they shall be removed from the moulds and immediately submerged in clean fresh water, and left there until taken out for breaking. The water in which they are submerged shall be renewed every seven days, and maintained at a temperature of between 58 and 64 degrees Fahrenheit. After they have been so taken out and until they are broken the briquettes shall not be allowed to become dry.

The briquettes shall be tested for breaking strength at 7 and 28 days respectively after gauging, six briquettes for each period. The breaking strength shall be the average tensile breaking strength of the six briquettes for each period. The briquettes to be tested shall be held in strong metal jaws of the specified shape, and the load steadily and uniformly applied, starting from zero, and increased at the rate of 100 lbs. per sq. in. of section in 12 seconds.

The breaking strength of the briquettes at 7 days after gauging shall be not less than 200 lbs. per sq. in. of section.

The breaking strength of the briquettes at 28 days after gauging shall show an increase on the breaking strength at 7 days and shall be not less than the number of lbs. per sq. in. of section arrived at from the following formula :—

$$\text{Breaking strength at 7 days} + \frac{10{,}000 \text{ lbs.}}{\text{Breaking strength at 7 days.}}.$$

The standard sand shall be obtained from Leighton Buzzard, be thoroughly washed and dried and shall pass through a sieve of 20 × 20 meshes per sq. in., and be retained on a sieve of 30 × 30 meshes per sq. in. The sieves shall be prepared from wire-cloth, the wires being ·0164 in. and ·0108 in. in diameter respectively. The wire-cloth shall be woven (not twilled), the cloth being carefully mounted on the frames without distortion.

12. Unless a specially quick setting cement is specified or required, it shall have an initial setting time of not less than 20 minutes and a final setting time of not more than 10 hours.

If a specially quick setting cement is specified or required, it shall have an initial setting time of not less than 2 minutes, and a final setting time of not more than 30 minutes.

The initial and final setting times of cement gauged as above shall be determined by means of the Vicat needle apparatus, in the manner specified.

13. The cement shall be tested for soundness by the Le Chatelier method, in the manner specified.

PLASTERS.

Plasters are pasty materials applied to walls, ceilings, etc., to give a hard, smooth finish. They resemble lime mortars in many respects, but serve a different purpose. Common plaster is made of lime and sand, with or without ¼ lb. of hair to each 1 cu. ft. of plaster. It is made harder and has smoother finish if 20 per cent. of plaster of Paris is added.

For *floors*, a hard-burned plaster of Paris is used, or a mixture of ordinary plaster with a slight excess of lime is laid, and then treated with zinc sulphate (white), iron sulphate (red), boiled oil (mahogany), or copal varnish.

Stucco for external use consists of 1 part of hydraulic lime to 3 parts of sand, but for more durable work a cement mortar (p. 391) is often used.

Rough cast is sometimes made of the same materials as stucco, or of cement mortar (p. 391).

Plaster of Paris is made by calcining gypsum and grinding the product. The resulting powder, when mixed with water, forms a smooth paste which rapidly sets to a white, solid mass.

Keene's, Martin's, and Parian cements are hard-setting forms of plaster of Paris. Keene's cement is made by soaking calcined gypsum in a solution of alum or borax and cream of tartar. For Martin's cement, a solution of potassium carbonate is used, and Parian cement is an intimate mixture of gypsum and borax which has been calcined and then ground to powder.

Artificial Stone.*

ARTIFICIAL BUILDING STONE, No. 1.—Mix 100 parts of hydraulic lime which has fallen to a powder with water to form a paste. To this add 250 parts of gravel and 50 of coal ashes or lixiviated wood ashes. The mass is then thoroughly mixed, and a sufficient quantity of water added to make the volume of the mass equal to 500 parts. It is then poured into moulds made of pine-boards, where it is allowed to remain until set.

No. 2.—125 parts of hydraulic lime which has fallen to a powder are mixed with a sufficient quantity of water to form a paste. To this are added 250 parts of ground oyster shells and 150 parts of ground peat ashes, and a sufficient quantity of water to make the bulk of the mass equal to 500 parts. It is then poured into moulds as in No. 1, and dried.

ARTIFICIAL STONE FROM QUARTZ SAND AND PLUMBIC OXIDE.—Ground quartz sand is mixed with 2 to 10 per cent. of finely-ground plumbic oxide. The harder the stones are to be, the more plumbic oxide must be used. The mixture is moistened with water-glass, again thoroughly mixed, and then pressed firmly into moulds. The resulting stone is dried and then burned.

VICTORIA STONE.—The refuse of granite quarries is broken up into pieces of suitable size, and 4 parts of the fragments thus obtained are mixed with 1 part of Portland cement, and sufficient water added to bring the whole to the consistency of dough. The mass is run into moulds, in which it is allowed to remain for several days, or until it has set solid. The blocks are then immersed in a solution of silicate of soda.

RANSOME'S ARTIFICIAL STONE.—Clean and dry sand and other suitable siliceous and earthy ingredients are thoroughly incorporated in a mixing mill with silicate of soda. The resulting pasty mass is then pressed into moulds of any required pattern or size, and when set sufficiently immersed in a solution of chloride of calcium. In the case of large pieces the saturation with chloride of calcium is facilitated by the use of an air-pump. The resulting reaction is the formation, by double decomposition of the ingredients, of an insoluble calcium silicate out of sodium chloride. The first-named forms a solid and indurate binding material for the stone, and the sodium chloride is removed by a subsequent thorough washing with water. This last operation is important, since, if the sodium chloride is not completely removed from the stone, it will make its appearance subsequently in the form of a white efflorescence on the surface.

TO IMITATE VARIEGATED MARBLE.—Mix hydraulic lime and ground marble and incorporate with the mixture a solution of alum and suitable colouring substances. Differently-coloured masses are then mixed together and cut into slabs.

ARTIFICIAL MARBLE.—The following mixtures have been recommended for making artificial marble. Grind and thoroughly mix comminuted stone, 280 parts; limestone or chalk, 140 parts; burned calamine, 5 parts; calcined felspar, 3 parts; fluorspar, 2 parts; calcium phosphate, 2 parts; water-glass, 40 parts.

On the addition of the water-glass the ingredients are quickly mixed, and thereupon pressed into moulds. The finished pieces are dried at a temperature gradually rising to 125° F.

* The manufacture of artificial stones, *lime-sand* bricks and blocks, is dealt with at length in 'Bricks and Artificial Stones of Non-Plastic Materials,' by A.B. Searle (J. & A. Churchill, London).

Asphalt Flooring.

8 lbs. of asphalt composition (1 ton asphalt, 20 lbs. mineral tar) will cover 1 superficial foot ½ in. thick. For goods warehouses thickness should be 1 in. For damp-course wall, ¾ in.

To Remedy Dampness in Walls.

1. If house shows damp on all sides just where walls rise from ground, cut out a course of bricks foot by foot, insert an asphalt damp-course, and re-brick up.

2. If wall becomes saturated by a stopped-up drain-pipe, remove plastering and re-point wall outside after wall has become dry. If it is inconvenient to renew plaster, the latter (although wet) may be varnished over with a solution of shellac in naphtha (4 ozs. shellac, 1 quart naphtha; this almost immediately hardens, and paper may be pasted over it.

3. A good coating of hot coal-tar laid on the exterior of a brick wall will prevent the entrance of damp, but should only be applied where it cannot be seen.

4. Another plan for walls above-ground is to mix 1 part of Portland cement with 2 parts of fine sand, and add water enough to bring the ingredients to the consistency of thick cream. Cover the brickwork with two coats of the mixture, and when it is quite dry finish with a coat of paint.

5. Re-plaster the inside of the wall with sand and cement impregnated with one of the secret waterproofing agents such as ' Bareau ' (see p. 400).

SECTION VIII

PART III

LATHING—PLASTERING—SLATING—GLAZING—PAINTING —PAPER-HANGING—PLUMBING—MOULDINGS.

Lathing and Plastering.

PLASTERING.

Coarse stuff is mortar composed of 1 part lime (carefully-slaked fat or pure lime is generally used) and 1 or 2 of sharp fresh-water sand, with 1 lb. hair to 3 cubic ft. of mortar.

Fine stuff is made of pure lime slaked with a little water, after which water is added to bring it to the consistency of cream; it is then left to settle, the superfluous water poured off, and the water evaporated until it is of proper thickness. In ceilings a small portion of white hair is mixed with it.

Bricklayers' and plasterers' putty is fine stuff brought to the proper consistency.

Gauged stuff is $\frac{3}{4}$ fine stuff mixed with $\frac{1}{4}$ plaster of Paris.

Common stucco is 1 lime to 3 or four clean-washed sand.

Bastard stucco is $\frac{2}{3}$ fine stuff and $\frac{1}{3}$ clean sand, with a little hair.

LATHING

is the first operation for ceilings and partitions; $\frac{3}{8}$-inch intervals are left between the laths, to key the plaster. Stronger for ceilings than for partitions.

One bundle of laths contains (nominally) 500 feet. Single fir laths are about $\frac{3}{16}$ in. thick; lath-and-a-half laths are full $\frac{1}{4}$ in. thick; double laths are about $\frac{3}{8}$ thick. They are about $1\frac{1}{2}$ in. broad. 1 bundle of 3-foot laths and 670 nails, or 1 bundle of 4-foot laths and 625 nails, will cover about 5 superficial yards.

Lath-and-Plaster, or *One-Coat Work*.—A coat of coarse stuff, $\frac{1}{4}$ inch to $\frac{3}{8}$ inch thick, laid on the laths and smoothed off with the trowel.

Lath, Plaster, and Set, or *Two-coat Work*.—The first, or 'pricking-up' coat of coarse stuff is scored with a birch broom or undercut with a lath, and a thin finishing coat of fine stuff or gauged stuff added.

Lath, Plaster, Float, and Set, or *Three-coat Work*.—When the pricking-up coat is dry, the surface is scored, and divided into 8-foot squares by *screeds* of coarse stuff, 8 inches wide, carefully levelled. These are then filled in with coarse stuff, floated carefully level. The finishing coat is then put on as before.

Lath Nails are either wrought, cut, or cast; the latter, being cheapest, are generally used. 1 inch, $\frac{7}{8}$ inch, or $\frac{3}{4}$ inch long, according as double, one-and-a-half, or single laths are used. $\frac{5}{8}$-inch cut nails run about 380 to the pound.

Materials.	1 in. Thick.	$\frac{3}{4}$ in. Thick.	$\frac{1}{2}$ in. Thick.
1 bushel of cement, or 1·28 cubic feet, will cover	$1\frac{1}{7}$ sq. yds.	$1\frac{1}{2}$ sq. yds.	$2\frac{1}{4}$ sq. yds.
1 cement and 1 sand "	$2\frac{1}{4}$ "	3 "	$4\frac{1}{2}$ "
1 cement and 2 sand "	$3\frac{1}{3}$ "	$4\frac{1}{2}$ "	$6\frac{3}{4}$ "

1 cubic yard of lime, 2 yards of sand, and 3 bushels of hair will cover 75 yards superficial, render and set, on brick, or 70 yards on lath.

Slating.

The following terms are used as in slaters' work:—

Head: the upper or edge top of slate *Back*: the upper or exposed surface of slate when laid. *Red*: the lower or under surface of slate. *Tail*: the lower or bottom edge of slate. *Margin*: the part of each course of slates exposed to view (*a–b*, fig. 699). *Gauge*: the distance battens are apart from centre to centre; required to determine the position of battens to receive the nails by which

the slates are secured. *Bond.*—When a joint of two adjacent slates is immediately in the centre of the slate, the tail end of which rests upon them, the slates are said to bond. *Lap*: the distance the tail of one slate overlaps the head of second course below, when slates are nailed near the centre, or the distance the tail of slate overlaps the nail-hole of second course below when slates are nailed near the head. The lap, in practice, ranges from 2½ inches to 4 inches, and averages as 3 inches. *Holeing*: the piercing of slates to receive nails. *Sorting.*—When roof is to be covered by slates of different lengths, they are regulated to proper dimensions, so that the largest slates may be nailed near the eaves, and the smallest at the ridge. *Eaves*: the lower part of slating hanging over a wall.

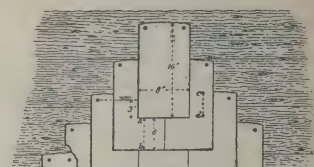

FIG. 699.

SIZES OF SLATES.

The sizes of slates in common use are as follows:—'Duchess' slates, 24 inches by 12 inches, for moderate flat roofs of ¼ pitch; 'Countess' slates, 20 inches by 10 inches, for roofs of ¼ pitch; and 'Ladies,' 16 inches by 8 inches, for roofs of ¼ pitch, the rule being, the steeper the pitch, the smaller the slate, and the more exposed the building, the greater the pitch of the roof.

Slates are laid on *boards* (fig. 699) or *battens* (fig. 700), the latter being the cheapest. Boards, ⅜ inch thick for Countess slates, and rafters not more than 18 inches in the clear, 1 inch or thicker, otherwise. Battens, 2 inches by ⅜ inch for Countess, with rafters 12 inches interval: 3 inches by 1 inch for Duchess. Slates are often *holed* 1 inch or 1½ inch from the head, as in fig. 699, but are better centre-holed, i.e. just clear of head of slate below, as in fig. 700.

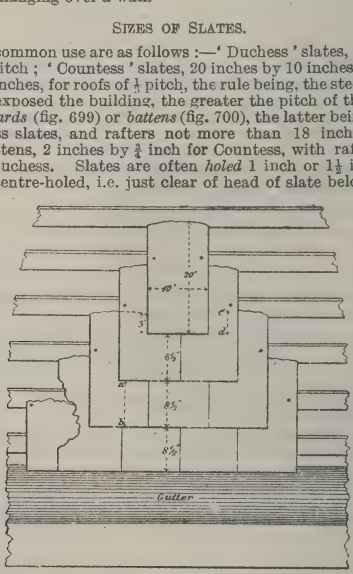

FIG. 700.

If a *good slate* is stood half its depth in water for several hours the moisture should not rise to the top.

SLATING NAILS.

Composition nails are recommended for all good work; they are stiffer than copper or zinc, present a brassy appearance, and are cheaper than copper nails. If iron nails are used, they should be galvanised, or boiled in linseed oil. Two to each slate, 1⅝ inch long for small slates, 1½ inch long for Countess, and 1¾ for Duchess slates.

Zinc and Copper Clips.—When a slate gets broken that is nailed to boarding and has to be repaired, narrow clips, about ½ inch wide, are pushed between the slates to catch the head of slate below. The new slate is then inserted, and the end of clip turned as a hook over the tail of the slate. When slates are nailed to battens, and the interior is accessible, they may be repaired by means of a piece of copper wire which is pointed at one end and driven into the batten or boarding at the head of under slate, passed between the side-joints of slates immediately above it, and lapped over the tail of the next slate but one above it. A man under the battens will secure a piece of copper wire to the battens, and then push the wire between the slates for the man above to clip over the tail of the new slate.

SIZE AND WEIGHT OF SLATES.

A thousand slates means 1,200. A square is 100 super feet.

Name.	Size.	Gauge for 3-in. Lap Nailed in Centre.	No. of Squares covered by 1,000 of 1,200.	Weight per 1,000 of 1,200.	Weight* per Square.	No. to Cover One Square.	Nails required per Square.	
							Iron.	Copper.
	Ins.	Ins.		Cwts.	Cwts.		No.	Lbs.
Smalls	12×8	4½	2·8	17½	6¼	430	860	5
Doubles	13× 6	5	2·5	18	6	480	960	6
Ladies	14×12	5½	5	31	6½	240	480	3½
„	16× 8	6½	4·5	25	5·5	300	600	3¾
Viscountesses	18×10	7½	6	36	6	200	400	2¾
Countesses	20×10	8½	7	40	5·7	171	342	4
Marchionesses	22×12	9½	9·4	55	6	130	260	3¼
Duchesses	24×12	10½	10	63	6	125	250	3
Imperials	33×24	13½	25	..	..	48	96	3
Rags	36×24	16½	30	..	..	40	80	3½
Queens	36×24	16¼	30	..	..	40	80	2

* The weights are for first quality Penrhyn or Bangor: second quality weigh about one-third more. As the sizes of slates of the same name sometimes differ slightly, the size required should be given as well as the name, when of importance. This Table allows about $\frac{1}{10}$th for waste.

'ÆGIS' ASBESTOS-CEMENT ROOFING SLATES.

These slates (*Turner Brothers Asbestos Co. Ltd., Rochdale*) are made in 'Honeycomb' and 'Diamond' patterns, figs. 700A and 700B. In these figs. E and UE indicate the eaves and under-eaves portions respectively.

The slates can readily be cut to fit hips, valleys, verges, round chimneys, and roof lights.

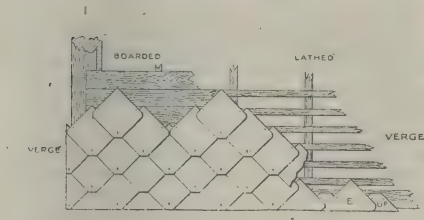

FIG. 700A.

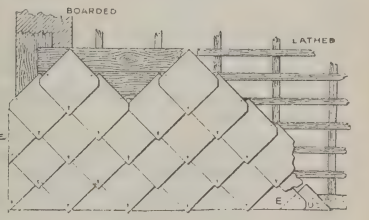

FIG. 700B.

Both the 'Honeycomb' and the 'Diamond' pattern slates are made to the sizes 11¾ ins. by 11¾ ins., 15¾ ins. by 15¾ ins., and may be cut and holed for laying with a 2¾ ins. or 3¼ ins. lap. The lap to be given is determined by the pitch of roof, position of building, and the prevailing climatic conditions.

For 'Fibrent' Asbestos Cement Slates see pp. 335, 336.

UNDERLINING.

Felt laid upon boarding under slates effectually keeps out the wet, and is a non-conductor of heat and sound; it should be battened over to preserve it.

Willesden Paper (*The Willesden Paper & Canvas Works, Ltd.*) is an excellent material for underlining. It is a good non-conductor, does not perish when shut up beneath slates or tiles, is waterproof, and will not allow rain or snow to penetrate, has no smell, even under the greatest heat, and lies very close on the roof.

Tiling.

For *plain tiles*, if each tile shows on the face 4 inches, 600 will be required to a square, *i.e.* 10 feet each way, or 100 square feet. In flat roofing, 210 tiles will be required for a square. 1 square weighs about 15 cwt. 100 plain tile laths 5 feet long = 1 bundle.

For *pantiles*, 180 to a 10-inch gauge, 164 to an 11-inch gauge, and 150 to a 12-inch gauge. The lap of the tile over the one below it will be just the difference between its length and the length of the gauge. 1 square weighs about 8 cwt. 12 pantile laths 10 feet long = 1 bundle. Fir tiling laths are 1½ inch by 1 inch; and oak tiling laths, 1¼ inch by ½ in. 1 square of tiling requires 1 bundle of laths, 150 nails, 1 peck of tile-pins, and 3 hods of mortar.

See also pages 335 and 424.

Glass and Glazing.

Sheet glass is that which is in ordinary use for windows, &c., and the usual glazing qualities are known as *best*, *seconds*, and *thirds*; a commoner quality, known as *fourths* or *coarse*, is also made, but is not much used.

The weights per foot super. are 15 oz., 21 oz., 26 oz., 36 oz., and 42 oz., the latter being nearly ¼ in. thick. As a rule, every $\frac{1}{16}$ in. may be taken as 13 oz. to the foot super.

In addition to the usual glazing qualities there are two others, called *picture qualities*, *A* and *B*, made in the 15 oz. and 21 oz., and one other, *C*, in the 26 oz. and 32 oz. thicknesses.

Sheet glass is sold by the foot super. of the required quality and weight, in *crates* of stock sizes for cutting up, or *squares* cut to order.

The ordinary stock sheets do not exceed in area 22 ft. super., in length 85 in., or in breadth 49 in., nor are they less than 11 ft. in area, 45 in. in length, or 34 in. in breadth.

The largest sizes that can be made in the various substances of sheet glass are as follows, *but the extreme limits of length and width cannot be combined in the same sheet* :—

	Extreme length.	Extreme width.	Extreme area.
15 oz.	60 in.	40 in.	15 ft.
21 „	90 „	50 „	26 „
26 „	90 „	50 „	25 „
32 „	85 „	48 „	21 „
36 „	70 „	44 „	17 „
42 „	70 „	44 „	15 „

The extreme area, taken in connection with the extreme length or width required in any particular case, will indicate approximately the corresponding limit of width or length.

Sheet glass obscured or frosted so as to appear like ground glass is made from any description of the third quality glass.

Sheet glass can be polished on face, bent to any required curve, or ground on the edges, as may be required.

Fluted sheet is glass rolled to form flutes or corrugations on both sides; which, while it secures privacy without obstructing the light, makes it much stronger than ordinary ground or obscured glass. It is made from 15 oz. to 32 oz. in weight, and in squares 60 in. in length and 38 in. in breadth. It can also be obscured if required.

White dappled is sheet glass about 21 oz. to the foot, the surfaces being mottled or undulatory, as its name implies. *White muffled* sheet is somewhat similar.

Patent plate is merely a superior kind of sheet glass, and is now not much used. It can be distinguished from British polished plate, by a more wavy appearance of the surface, as well as by the air bubbles, which are *oval* in patent plate and *circular* in British plate. It is made in four thicknesses—viz. $\frac{1}{10}$, $\frac{1}{12}$, $\frac{1}{16}$, $\frac{1}{20}$, and $\frac{1}{8}$ in.—and three qualities—bests, seconds, thirds—in each. $\frac{1}{10}$ in. and $\frac{1}{12}$ in. are generally used for picture purposes, and $\frac{1}{20}$ in. and $\frac{1}{8}$ in. for coach plates. It can be supplied *smoothed* or *finely ground*, in sheets 50 in. in length or 36 in. in width.

Polished or *British polished plate* is the best article made, and is kept in stock sheets up to 100 ft. super., or 160 in. long or 104 in. wide, but can be made in larger sheets if specially ordered. The usual thickness is ¼ in., but it can be obtained ⅛ in. thick, varying by $\frac{1}{16}$ in. up to 1 in. in thickness. It is manufactured in three qualities, known as *ordinary* and *best glazing*, for windows, etc., and *silvering quality*, for mirrors, etc. It can be bent to any desired curve, and the edges can be ground or polished. If scratched the surface can be repolished or resilvered at any glass works.

Rough cast plate is the cheapest quality of plate glass, and is made in plates even exceeding 100 ft. super., but the stock sizes run up to about 60 ft. superficial. Its thickness ranges from ⅛ in. to 1 in. It can be bent to any curve, or ground on one or both sides if required. From its

F. 413

strength it is very useful for risers to steps, glazing pavement lights, and similar rough work where light has to be transmitted.

Plain and *fluted rolled rough plate* is principally used for railway roofs, factories, workshops, etc., and other purposes where the object is to intercept the vision but not the light. The *plain* is rolled with fine lines on the surface; the *fluted* is either of the small pattern, with about 11 flutes to the inch, or the large pattern, with about 4 flutes to the inch. It is made from $\frac{1}{8}$ in. to $\frac{3}{8}$ in. thick, in stock sizes not exceeding 25 ft. super., or 130 in. in length, or 46 in. in breadth. It can be bent to curves, or obscured on the rough side.

Diamond and *quarry rolled rough plate* is principally used for churches, chapels, schools, lecture halls, etc. The diamond rough plate has a bright and brilliant appearance. The pattern is of a lozenge shape, and in relief upon the body of the glass. The quarry rolled is in imitation of, and is used as a substitute for, leaded quarries, and is made in either *large* or *small* patterns. It is made from $\frac{1}{8}$ in. to $\frac{1}{4}$ in. thick, in sheets from 20 in. to 34 in. wide and up to 100 in. long.

Chequered rolled plate is similar to *diamond*, but the pattern is square. It is principally used for screens, door panels, etc.

Rolled plate corrugated one side is about $\frac{1}{4}$ in. thick, and is made in sheets up to about 110 in. long and about 36 in. wide. It is used for glazing in any position where extra light is required and opaqueness a necessity, and is suitable, when silvered, for reflectors.

Figured rolled glass is made in a variety of patterns known by distinctive names, such as 'Muranese,' 'shell,' 'Arabesque,' etc., and is made either white or in various tints.

Patent wire rolled glass consists of a sheet of glass, about $\frac{1}{4}$ in. thick, having wire netting embedded in its centre. It is extremely useful for many purposes.

Rolled cathedral glass weighs about 21 oz. to 26 oz. to the foot super., but can be made thicker if required. It is made either in white, pot metal colours, or cathedral tints. This last term is applied to light tints of no positive colours, which are suitable for glazing the windows of churches throughout.

Coloured and *stained glass* is made from 15 oz. to 32 oz. in weight, and in sheets not above 48 in. long or 34 in. wide, in a variety of colours, which are known as *flashed*, in which the body is of ordinary sheet glass thinly covered on one surface only with coloured glass, or *pot metals* in which the glass is coloured throughout. This glass can also be *sanded* or *obscured*.

PUTTY, PAINT, AND SOLDER.

The glazier's, like the painter's, putty is merely composed of whiting and linseed oil well beaten up.

In order to prevent the constant expansion and contraction of large panes of glass, especially in tap-lights, from loosening of the putty, tallow may be mixed with the latter, forming what is called *thermoplastic putty*, which, by retaining its pliability, gives and takes with the glass.

The priming and paint used by the glazier are the same as used by the painter.

The solder used for lead glazing is the plumber's *fine solder*, or 1 lead to 1 tin.

Painting.

All surfaces to be painted should be smooth, clean, and well dusted. The first operation in painting resinous woods, such as fir, is *killing the knots*, or treating them so as to prevent the resin or turpentine from exuding and ruining the paint. This may be done by painting the knots over with hot lime, and, when dry, ironing them with a hot iron, and then painting them smooth: or leaving the lime on for about 24 hours, scraping it off, and then painting with red and white lead and linseed oil, and, when dry, pumice-stoning the knots smooth. But these processes take time, to obviate which a liquid called *patent knotting*, chiefly shellac and naphtha, is much used. It forms a skin over the knots, and by drying in about 5 minutes allows of the painting going on at once. *Red-lead knotting*—made by grinding red lead in water mixed with strong glue size, and used warm—is, however, considered preferable to patent knotting, and dries in about 10 minutes.

The first coat of paint is called the *priming coat*. This in ordinary lead painting is composed of red lead, or red and a little white lead, mixed with raw linseed oil, a little litharge, and burnt copperas ground very fine in turpentine as a drier, the object being to fill the pores of the wood with oil before applying the colouring coats, which would otherwise be sucked up and wasted by the wood.

After the priming comes the stopping, or filling up all nail-holes, etc., with putty, which if applied before the priming, would become loose from the wood drawing the oil out of the putty, and allowing it to shrink.

After all defects have been made good, and the work has been rubbed smooth, the colouring coats are applied, the second coat, or first after priming, being diluted with about one-third turps, the third coat having the oil and turps in equal proportions, and the fourth coat one-third oil to two-thirds turps. If not to be painted white, the second coat should approximate to the required colour.

When, as in drawing-room work, it is desirable to avoid the glossy surface of oil paint, a fifth coat, for which all turps and no oil is used, is added, and is called a *flatting* coat, and should be laid on before the last coat has become hard. It will not admit of washing, as oil paint will, and therefore is not suitable for outdoor work.

Varnish adds greatly to both the appearance and durability of paint. A priming coat followed by a dark coat, such as a chocolate or purple-brown, and finished off with a coat of common varnish, is cheaper than, and as durable as, 4 coats of colour; it looks better, is more rapidly executed, and stands washing well. A single coat of gum-lac or good resin, dissolved in linseed oil to about the consistency of cream, and coloured as may be required, also forms a good and durable covering.

Walls may also be coloured and varnished thus: First, apply at boiling heat 2 coats of whiting mixed with strong glue size, then fill up defects with mastic in water, rule smooth with pumice stone, and cover with 2 coats of coloured varnish, the first coat mixed with one-fourth of the required colour, and the last coat with only half as much colour. The colour should be ground very fine, and the varnish should be white spirit varnish.

Plaster, being very absorbent, is often primed with glue size and then covered with 4 coats of colour (if the ordinary lead paints are used), and a flatting coat can be added if desired; but the best plan is to apply a priming coat of boiled oil quite warm, and when dry and hard add a thin coat of weak size tinged with red lead, in order to stop all absorption and give the work a uniform appearance, and finish off with 2 coats of oil paint, and a flatting coat if required; or 2 coats of coloured varnish can be applied as described above.

In painting on plaster, in order to guard against damp injuring the paint, it is safer to distemper the walls for the first two years, and then wash it off and paint, taking care that the walls are perfectly dry. If the distemper is not greasy or dirty, it is better to merely brush it well down with a dry brush, and paint over it without any washing.

With the ordinary paints, new wood or ironwork requires 4 coats, including the priming coat, but exclusive of any flatting coat, and old paint should have 2 coats for inside and 3 for outside work.

Painting Fresh Cemented Surfaces.

The McNicholl process seems to be the best treatment yet devised for coating a fresh cemented surface to enable it to be painted. It consists of zinc sulphate, 5 lbs. to the gallon of soft water. The zinc sulphate forms a chemical compound that prevents the alkali from attacking the paint coating, afterwards applied. This process is also good for interior walls, over Keene's or Portland cement. When it is dry apply a coat of either pure raw linseed oil or an oil paint, thinned out with benzene. (*Contract Record.*)

Valuing and Estimating Painters' Work.

The rule in measuring painters' work is to take wherever the brush goes, by the *yard superficial* in the case of large surfaces, such as walls, doors, etc.; by the *foot run* in the case of narrow surfaces *cut-in* on both edges, as in skirtings, where the paint has to be run to a line both at top and bottom, to avoid painting the floor or wall; and by the *number* in the case of separate pieces, such as chimneypieces, newels, balusters, brackets, gratings, etc. In iron railings and other open work each side is measured by the yard superficial, as if it were a plain surface, and if ornamental each side is doubled, or a fair extra allowance made according to the nature of the work.

The outsides of ordinary-size frames, being *cut* to the wall, the insides, as well as when there are no linings, as in stores, riding-schools, etc., are taken by the number. In cases of sash-frames with mullions or transoms each division is taken as one side of a frame.

It's Ready to use!

Guaranteed Pure

MINERVA PAINT

(RED LABEL)

6 WHITES, PINK PRIMING & 120 SHADES

Sold in 1 *Gall.*, ½ *Gall.*, *Quart and Pint Cans*
Also in 5 *Gall. Drums and* 40 *Gall. Barrels*

For Paint work of any kind it pays to use or specify 'MINERVA.' It is beautifully ground, finely mixed, and covers a larger area with a better finish than any other paint of equal weight, whether hand or machine made.

(BLUE LABEL)

THREE KINDS ONLY: (1) UNDERCOATING (2) FLAT WHITE FINISHING for inside use only (3) GLOSS FINISHING for inside or outside use. Made of a natural pigment suspended in a special medium, this paint flows out very smooth, spreads just nicely under the brush and finishes beautifully

DEYDOL
DISTEMPER
WHITE AND 60 COLORS.

For Workshop or Factory Walls and Domestic Decoration, there are many advantages in 'DEYDOL.'

SANITARY
Health of Workers

The DEYDOL wall surface is in the highest degree SANITARY—on this head alone it has secured the certificate of the Institute of Hygiene—the first distemper to do so.

* * * *

WASHABLE
Constant Cleanliness

DEYDOL'D Walls are WASHABLE. A light sponge down with clean water instantly removes dirt marks, soilings, etc.

* * * *

DURABLE
Less frequent Renewals

Next to Oil Paint, DEYDOL is the most durable wall covering in existence—a point of particular interest in commercial usage.

* * * *

Shade Book and Detailed Information can be obtained post free from the Sole Manufacturers:

PINCHIN, JOHNSON & Co., Ltd.

(Associated with WILKINSON, HEYWOOD & CLARK, LTD.),
Varnish, Color, Paint, and Enamel Manufacturers,
General Buildings, Aldwych, London, W.C. 2

Also please see pages 415 964, 965, 1966, 1967, 2353, 2354 for particulars of other Special Paints.

The sashes themselves are paid for by the *dozen squares*, the price being for one side only, the number being doubled if painted at the same cost on both sides.

Letters and figures are paid for by the *inch in height* as plain or ornamental.

Common colours include *lampblack*, *red* and *white lead*, *Venetian red*, *ambers*, and all other *common ochres*, such as *greys*, *buffs*, *stones*, *etc.* *Superior* or *ornamental colours* include *bright yellows*, *warm tints*, *blues*, *mineral greens*, *etc.* Some colours, such as *verditer*, *pea-greens*, *rich reds*, *pinks*, and *bright blues*, are charged at a higher rate still, as *delicate tints*.

The following are the yards super which a fixed amount of material will cover in each coat :—

First coat, or priming	10 lbs. white lead 1 oz. red lead	2 ozs. litharge* 4 pints linseed oil	63 superficial yards.
Second coat	10 lbs. white lead 2 ozs. litharge	2½ pints linseed oil* 1½ pint spirits of turpentine	100 superficial yards.
Third and fourth coats	10 lbs. white lead 2 ozs. litharge*	2 pints linseed oil 2 pints spirits of turpentine	113 superficial yards.

For outside work, when exposed to the sun, more turps should be used to prevent the paint from blistering, and only *boiled* linseed oil should be used. For inside work, raw linseed oil may be used, but the less oil the less gloss. For the flatting coat, the colour being ground in oil, only turps is added.

For coloured paints the last two coats have the colour added to the composition in the proportion of 1 to 2 lbs. for every 10 yards of surface to be painted; and the quantity of white lead is reduced in proportion.

One pint of varnish will cover about 16 yards : 1 coat.

See also WORKSHOP RECIPES.

SPRAY PAINTING.

Tests carried out on paint-spraying machines have shown that spraying requires approximately 10 per cent. more paint than brushing when the surface being treated is an iron roof, while brushing requires approximately 200 per cent. more labour than spraying. On exterior brick walls, spraying requires 7 per cent. more paint than brushing, while brushing requires 109 per cent. more labour than spraying. On interior ceilings and walls of plaster, spraying requires 40 per cent. more paint than brushing, but gives a better hiding in one coat. On similar work, brushing requires 160 per cent. more labour than spraying, and gives a poorer hiding in one coat. Although it has not been possible as yet to arrive at a definite conclusion confirming the relative durability of spraying as compared with hand-painting, it is claimed that the investigations so far made tend to support the belief that the spraying work will last longer.

Distemper.

DEYDOL DISTEMPER.

Deydol Distemper (*Pinchin, Johnson & Co. Ltd.*) is a sanitary wall covering which is washable, weather-proof, and fire-resisting. It is in the form of paste which is thinned with clean cold water or DEYDOL PETRIFYING LIQUID, to the consistency of thick cream, and then applied with a distemper brush. Deydol gives a soft, velvety, and even flat finish, and is prepared in a number of colour tones. The surface may be stippled to enhance the finish, which is washable when thoroughly set. The distemper may be used for outdoor as well as indoor work, and may be applied over brick, stucco, cement, stone, plaster, wood, iron, or other usual building material, provided a little pale boiled linseed oil is added to the paste before thinning as above.

One and a half pints of liquid to 14 lbs. of paste is the average proportion, and this will make sufficient distemper to cover about 600 squre feet of normal surface, one coat.

Where the plaster or cement has a tendency to sweat it causes the colour to run this can be prevented by a coat or two of 'Deydolene,' which is a special material for usage as a first coat in above or other abnormal conditions. It insulates lime action, stops suction, sweating, patches, spots, sheariness, discoloration, and other troubles that originate in certain surfaces. Moreover, it holds up the full beauty of the succeeding Deydol Finish, and is a most effective damp resister. Where necessary, Deydol Distemper can be varnished over as an additional protection for surfaces that are subject to heavy wear and continual brushing against. GRIPON SUPERVAR is particularly suitable over Deydol.

Whitewash

is used for common walls or ceilings where for sanitary reasons a frequent application is necessary.

It will not stand rain, and adheres badly to very smooth or porous surfaces. It is cheap, and when used for sanitary reasons should be made of hot lime and applied at once.

Whitewash is improved by adding 1 lb. of tallow (free from salt) to every bushel of lime.

SIZE.

Size should be made from the best glue. The glue is prepared by boiling the skin and horny parts of animals. To make size, glue is placed in a pot and covered with water. When melted it is thinned by the addition of more water. One pound of glue makes one gallon of size. Size is used with colouring matters to make them adhere to surfaces.

* Or ½ oz. of burnt white vitriol and 1½ oz. of litharge.

WHITING.

Whiting is made by washing pure white chalk in a wash mill with water to a creamy consistency. The cream flows to settling tanks or backs. When settled, the spuernatant clear water is run off, and the upper sediment is scooped out by long-handled scoops and laid in shovelfuls on a floor of chalk blocks. The chalk absorbs the moisture, and the partly dry slabs (or balls, when so-called hand-made ball is made) are piled on open wooden racks above the chalk floor until air dried. Bulk whiting is dried on fire-heated floors of iron plate. The lower sediment in the backs is returned to the wash mills for cement making or is sold as whiting sand.

Whiting is mixed with water and size for whiting ceilings. It will not stand weather, nor unlike lime whitewash, has it any purifying effects.

100	10	12	13	15	16	18	20	21	24	24

Paper for wall decoration is sold by the *piece*. A piece of English paper is supposed to be 12 yds. long and 20 ins. wide when hung; therefore each yard run will contain 5 ft. super, and each piece 60 ft. super; consequently the feet super of surface to be papered divided by 60 will give the number of pieces of paper required, any odd number of yards being taken as a piece. With common patterns 1 piece in 10 should be added to make up for waste in cutting and fitting the patterns in, whilst in large patterns 1 in 7 would not be too much. In all cases a liberal allowance should be made, as it is useful for repairs, the same pattern not being always procurable when required.

A gallon of paste will hang 5 pieces of English paper, a quart of flour being required for each gallon of paste; sometimes a little alum is used to increase its strength, but makes it harder

and prevents it spreading so well. One gallon of boiling water to 2 lbs. of flour and 1 oz. of alum is a common proportion in making paste. The thinner the paste can be made, the better; and it should be well strained before using.

Before papering, the walls should be stopped, pumiced, and sized.

In paperhanging, the trimmed edges of the paper should face the light, to prevent any shadow marking the joints, and should be truly plumb; the pattern should accurately join.

In all cases of re-papering walls, the old paper should be stripped off and the walls scraped, washed, and stopped, previous to hanging the new paper. Papering-over old paper must never be allowed; many rooms which smell close and unhealthy owe it all to several thicknesses of old paper and paste decomposing on the walls. Disease and death have been clearly traced home to the omitting to strip off the old paper before re-papering.

Flock papers when old, instead of being stripped off, can be painted; they will absorb three or four coats of paint; but it produces a very good effect, from the embossed pattern standing out on the surface.

Mouldings.

Nos. 1 to 32, fig. 700C, show various forms of mouldings. The following are those in most general use:

Nos. 2, 17, 26.—For inner face of window-frames, and the outer and inner faces of door-frames.

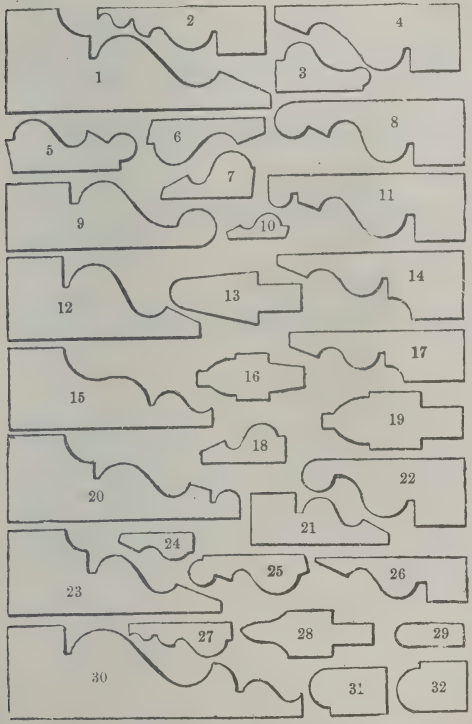

FIG. 700C. Mouldings.

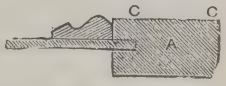

FIG. 701. Moulding.

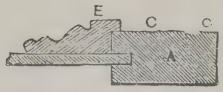

FIG. 702.—Bolection Moulding

Nos. 18 and 24.—For edging the framing of panels of doors formed of styles and rails.

Nos. 13, 16 19, 28.—Rebated mouldings for the reception of glass; may be used as sash-bars or for the bars of window-frames.

Nos. 31 and 32.—Beadings for capping matchboarding carried part way up a wall from the flooring.

No. 29.—Beading or slip for placing on either side of a window-frame, to confine the sashes in their proper place.

If the moulding does not project beyond the face, C, C, of the frame, A, as in fig 701, it is simply described as a *moulding*.

If the moulding, fig. 702, projects beyond the face of the frame, A, making a narrow projecting framing, E, between the frame of the door and the curved part of the moulding, it is described as a *bolection* moulding.

Plumbing.

Lead.

For roofs, flats, gutters, bottoms of cisterns, and sinks, use 7 lbs. per foot super.

For hips, ridges, small gutters, valleys, and sides of valleys, use 6 lbs. per foot super.

For flashings use 5 lbs. per foot super.

For soil-pipes use 8 lbs. per foot super.

Gutters should have a fall of at least 1 in. in 10 ft., better 1½ in. Flashings should have 3-in. laps, ridge and hip joints 4-in. laps, valley and roof joints 5-in. laps.

Lead in gutters should turn up under slates, etc., from 7 ins. to 9 ins. according to pitch of roofs, and against walls from 5 ins. to 8 ins., and be covered with a flashing, or 'apron,' the upper edge of which is let into a mortar-joint a little above the gutter lead, the lower edge overlapping the latter at least 3 ins.

No sheet of lead should be laid in a greater length than 10 ft. or 12 ft. without a drip or vertical overlap at least 2 ins. deep, to allow of expansion. Soldering should be avoided, if possible.

Zinc.

The gauges of zinc recommended for roofing purposes are Nos. 13, 14, 15, and 16, the weights per sq. ft. of each gauge being respectively 16 ozs. 15 drs., 18 ozs. 12 drs., 21 ozs. 12 drs., and 24 ozs. 12 drs. The sheets usually measure 8 ft. × 3 ft.

Rain-water Pipes.

These are made of cast iron, generally in 6-ft. lengths. The round pipes vary in diameter from 1½ in. to 8 ins. The square pipes are made from 2½ ins. × 2 ins., up to 6 ins. × 6 ins. The 3-in. round pipe is a size largely used.

Corrosion of Zinc and Lead Water Pipes.

Zinc water pipes in contact with mortar containing gypsum become in a relatively short time corroded and eaten through in places. Where the surface is wetted and quickly dried, a protective coating of oxide is formed; but where the contact with running rainwater is prolonged, as in the case of roofing plates and gutters, the possibilities of energetic action must be reckoned with. The most active agent of destruction is sulphate of lime. Zinc is energetically attacked by mortar containing gypsum sand, but only feebly by mortar containing limestone sand alone, or with an addition of gypsum. Lead, on the other hand, is energetically attacked by limestone alone and with an addition of gypsum, but only feebly by gypsum sand mortar. Both metals are strongly attacked by pure cement, but the destructive action is lessened in progressive measure by the addition of sand. Hence zinc should be put in contact only with limestone (carbonate) mortar, and lead only with gypsum (sulphate).

SECTION IX

Consulting Advisor on Clay Products.)

CLAYS AND EARTHS.

For engineering purposes, clays and earths may be regarded as (1) substances which must be excavated and transported from their present situation; (2) the raw materials from which earthwork, puddle, etc., are made; and (3) the raw materials used in the production of bricks, drain pipes and many other articles employed by engineers. The term 'clay' in the broadest possible sense is applied to a material which is tenacious and plastic when wet. Such clays may contain only a small proportion of true clay, together with a large proportion of inert material such as sand. For many engineering purposes a perfectly pure clay would be useless, as it might be of so fine a texture and so highly plastic that it would shrink excessively on drying, and it would be extremely difficult to make into bricks or other desired articles. When made, these articles would be deficient in certain important properties, such as resistance to crushing, impermeability to water, etc.

The term 'earth' is usually applied to a friable material partaking of the general properties of soil, though not necessarily of any agricultural value. It usually consists chiefly of inert material, the particles of which are united by a very variable proportion of clay, humus, or other adhesive. Hence the 'earths' are often regarded as 'clays' of low plasticity, but both these terms are used very loosely by many engineers and no really satisfactory definition of them has yet been formulated.

In selecting a 'clay' or 'earth' for any given purpose, the engineer must, therefore, decide what properties are essential to his requirements and must endeavour to find a natural material possessing these properties, or to prepare a mixture of two or more materials which suit his purpose.

The chemical and physical properties of 'clays' depend chiefly on the composition and plasticity of the material, it being obvious that a 'clay' containing 50 per cent. of quartz-grains must behave very differently from one which consists wholly of 'true clay.' The *plasticity* of clays varies with the nature of the clay and the amount of water present. Dry clays are friable and devoid of plasticity; on mixing clay with an equal weight of water a liquid slurry or slip is formed which is not really plastic, but becomes so when a suitable proportion of the water has been removed by evaporation or otherwise. No generally accepted explanation of the cause of plasticity has been published; this property may be due to the presence of colloidal particles which may be derived from the clay itself or from impurities which have become associated with it. The purest clays—e.g. 'china clay'—are very feebly plastic; the highly plastic ball clays which are supposed to have been derived from them are rich in carbonaceous matter, to which their plasticity is sometimes attributed. The clays commonly used for bricks, pipes, terra-cotta, etc., are never pure; they are naturally-occurring complex mixtures possessing the requisite properties to make them useful for specific purposes.

It is a great mistake to suppose that any plastic 'clay' can be made into bricks, or that any 'system' of manufacture is equally suitable for all 'clays.' On the contrary, the manufacture

of clay products is in reality so complex (notwithstanding its apparent simplicity) and the ordinary manufacturer depends on the simultaneous occurrence of so many fortuitous circumstances that it is not surprising that many firms fail to manufacture clay goods of uniform quality.

PUDDLE.

Puddle is a highly plastic paste made by mixing 'clay' with about one-fifth of its weight of water, the precise amount depending on the plasticity and dryness of the 'clay.' A perfectly pure 'clay' does not usually produce good puddle, as it is either deficient in plasticity (like china clay) or it shrinks excessively. The former defect can only be remedied by the use of a more highly plastic material; excessive shrinkage may be prevented by mixing a suitable proportion of sand with the clay. For the best results, a piece of puddle when dried should not shrink more than $1\frac{1}{2}$ in. per linear foot; on the other hand, it should not shrink less than $\frac{3}{4}$ in. per linear foot or it will probably not be sufficiently impermeable to water.

The materials used must be carefully selected and thoroughly well mixed; some contractors are very careless in this respect and will use anything which has been passed through a pug-mill. The correct consistency for good puddle is that at which that paste can be squeezed easily in the hand without any appreciable quantity adhering to the latter when the pressure is released. Puddle made of the consistency of porridge is much too soft for best work, though it is better than an over-dry or badly mixed stiff paste.

Where possible, the materials used for making puddle should, before being mixed with water, be passed between a pair of rollers placed not more than $\frac{1}{8}$ in. apart, so as to crush any stones or coarse gravel present. It is also desirable that all roots and large stones should be picked out before sending the 'clay' to the mixer.

BRICKS.

Many kinds of bricks are in use. The most important are: *Common Bricks*, used for ordinary building purposes; *Facing Bricks*, used for external work where appearance is important; *Paviours*, used for yards, footpaths and other locations where a hard-wearing and impervious brick is required (for *Road Bricks* see page 732); *Blue Bricks*, which are similar in many respects to 'pavviours' and are employed where exceptional strength and impermeability are important; *Stock Bricks*, which are practically the same as 'common bricks,' but have usually been burned in a clamp instead of in a kiln; they have proved exceptionally resistant to the climatic conditions of London, but are seldom, if ever, used in other large industrial centres (in some localities the term 'stock bricks' relates to 'facing bricks').

Bricks are also known according to the manner of their production. Thus, *Malms* contain a large proportion of chalk, either naturally or artificially mixed with the clay; *Wire-cut Bricks* are made by cutting up a column of clay issuing from a machine, by means of wires; *Pressed Bricks* have been made in presses; *Semi-plastic* or *Stiff Plastic Bricks* have been made from a paste which is stiffer and less plastic than that used for hand-moulded or wire-cut bricks; *Semi-dry Bricks* are made by compressing the powdered clay in powerful presses instead of first converting it into a paste.* *Place Bricks*, *Grizzles*, and *Chuffs* are inferior bricks which are soft through insufficient burning; *Crozzles* are excessively hard, misshapen bricks which have been partially melted and overheated. *Rubbers* and *Cutters* are soft, sandy bricks.

Glazed Bricks are used where a smooth and impervious surface is required (see 'Glazed Tiles.').

Sand-lime Bricks † are made of sand mixed with about 6 per cent. of lime and matured in an atmosphere of steam under pressure. They have never become very popular, chiefly on account of the abundance of clay bricks and stone, but in localities where sand is plentiful and clay scarce they appear to be an excellent substitute for clay bricks.

Several attempts have been made by various Government officials to extend the use of sand-lime bricks, but such efforts have proved abortive, as such bricks are much more difficult to make at a profit, and there is a larger proportion of unsaleable waste than with clay bricks. Some of the statements respecting the speed of production and cost for manufacture of sand-lime bricks, published in certain Government publications, are by no means correct if applied to average conditions.

Cement-concrete Bricks.†—These bricks have attracted attention, but are not so suitable as larger blocks of concrete for general purposes, as the cost of production is relatively high. Such bricks are made in precisely the same manner as concrete blocks—i.e. from a mixture of Portland cement with six times its volume of one of the following aggregates:—sand, destructor, furnace-, or boiler-clinker, ashes, quarry waste, and broken bricks or stone. The use of these bricks appears to be limited in practice to districts where clay bricks cannot be obtained at a reasonable price, and even then concrete blocks or mass concrete would be much cheaper, as the manufacture of such bricks is not nearly so simple as a description of the process may imply

* For further details respecting the manufacture of bricks see 'Modern Brickmaking' by A. B. Searle (Scott, Greenwood & Son, London).

† See 'Bricks and Artificial Stones of Non-Plastic Materials' by A. B. Searle (J. & A. Churchill, London).

Engineering Bricks is the term usually applied to bricks of an exceptionally dense and vitreous character, of which the best known are the *Staffordshire* blue bricks. These owe their unusual strength and impermeability to the fact that they have been burned under such conditions that the particles composing them are united very firmly by means of a film of clinker surrounding each. For purposes where a somewhat weaker brick has ample strength, well-made *pressed* or *stiff plastic* bricks are usually satisfactory and much less costly, but they are more porous and therefore less suitable for supporting heavy masses of material on a boggy or damp subsoil. Bricks for *boilers* should be accurate in size and shape so as to enable the thinnest possible joints to be used. In order to prevent undue leakage they should be glazed or painted with tar or other impervious material. For boiler *blocks* see Section XXIX, Part II.

For *fireboxes, furnaces*, etc., firebricks and blocks are employed.

Colliery Bricks are usually of very poor quality, due to their being made from unsuitable material, or from good clay which has been spoiled by mixing it with rubbish.

There is serious need for great improvements in the manufacture of bricks in many collieries, and those firms who have called in a competent and independent advisor have found that it has paid them well to follow his advice. The services of unemployed foremen, machinery manufacturers, and kiln builders, in this connection, are seldom satisfactory, as their recommendations are unduly biassed.

Crushing Strength of Bricks.

Opinions differ greatly as to the respective values of different kinds of bricks, and as the crushing strength of bricks taken from the same works at different times varies 25 per cent. and even more, it is clear that no comparison of crushing strength tests can be of much value in deciding between various kinds of bricks. The chief use of the tests is in fixing a minimum crushing strength which shall ensure the safety of the structure, but as the strength of even the commonest bricks is much greater than that of average brickwork (the mortar being usually weak), it is difficult to stipulate any satisfactory minimum strength for bricks.

The following figures are the averages of a large number of bricks, but it must be clearly understood that bricks from any given works may be either much stronger or much weaker than the ones mentioned.

Description.	Crushing Commences.	Ultimate Crushing.
	Tons per square foot.	Tons per square foot.
Common stocks	40–60	80–120
London best stocks	80–140	100–180
Gault white, wire-cut	40–120	135–200
Aylesford, red pressed	70	140
Manchester, common red	75	120
,, wire-cut	85	260
Accrington, plastic	115	250
Leicester, wire-cut	115–250	230–340
Rugby, common red	160	190
Fletton	125–200	170–250
Notts.	60–300	120–400
Ruabon.	360	—
Terra-cotta blocks	—	100–260
Glazed bricks	70–165	165–175
Stourbridge firebricks	90–160	110–210
Sand-lime Bricks	150–200	180–230

The crushing strength of brickwork is shown on pp. 253, 384.

Sizes of Bricks.

In many countries there is no official standard; the following are average sizes:—

Standard Sizes of Bricks in different Countries.*

Country.	Length, inches.	Breadth, inches.	Thickness, inches.
Great Britain	9	$4\frac{1}{8}$	$2\frac{5}{8}$ †
Germany	10	$4\frac{1}{2}$	$2\frac{3}{8}$
Austria	$11\frac{5}{8}$	$5\frac{5}{8}$	$2\frac{3}{8}$
France	$8\frac{3}{4}$	$4\frac{3}{4}$	$2\frac{3}{4}$
Italy	9	$5\frac{1}{2}$	$2\frac{3}{4}$
Holland and Belgium	$9\frac{3}{8}$	$4\frac{3}{4}$	$2\frac{1}{4}$
Switzerland	10	$4\frac{1}{4}$	$2\frac{1}{4}$
Russia (varies greatly).	$11\frac{1}{2}$	$5\frac{1}{2}$	$2\frac{1}{2}$
United States	8	4	$2\frac{1}{4}$

* See also p. 374. † In Scotland, $2\frac{11}{16}$ in. or 3 in.

Specification for Bricks.

The sizes of bricks vary in different parts of Great Britain, but there are many advantages in adopting the Specification of the Royal Institute of British Architects as follows:—

The Royal Institute of British Architects' standard size lies between—length, 8¾ ins. and 9 ins.; breadth, $4\frac{5}{16}$ ins. and 4⅝ ins.; thickness, 2⅝ ins. and $2\frac{13}{16}$ ins.

The method of measuring the bricks as set out in the standard specification is as follows:—

(1) The length of the brick should be double the width plus the thickness of one vertical joint.

(2) Brickwork should measure four courses of bricks and four joints to a foot.

Joints should be ¼ in. thick, and an extra $\frac{1}{16}$th, making $\frac{5}{16}$th, for the bed joints to cover irregularities in the bricks. This gives a standard length of 9¼ ins. centre to centre of joints.

The bricks, laid dry, to be measured in the following manner:—

A. Eight stretchers laid square end and splay end in contact in a straight line, to measure 72 ins.

B. Eight headers laid side to side, frog upwards, in a straight line, to measure 35 ins.

C. Eight bricks, the first brick frog downwards and then alternately frog to frog and back to back, to measure 21½ ins.

A margin of 1 in. less will be allowed as to A and ½ in. less as to B and C.

Tests of Bricks.

All dry bricks should *ring clearly* when two, held in the hands, are struck sharply together. If a dull sound is emitted the bricks are either saturated with water or they have not been sufficiently well burned.

The *porosity* of bricks is usually tested by soaking them in water, wiping dry and noting the increase in weight. Whilst many good building bricks will absorb one-fifth of their weight of water, this is no criterion of the value from an engineering standpoint; on the contrary, engineers usually prefer bricks with low porosity on account of their greater strength.

Rattler Test.—In the United States, and to a much smaller extent in this country, engineering bricks are tested for toughness and resistance to abrasion by placing a weighed quantity of them in a cylinder with steel balls and rotating the cylinder a thousand times in about half-an-hour.* The contents of the cylinder are then removed, all pieces of brick larger than 1 in. diameter are picked out and reweighed. The loss in weight is regarded as a measure of the inferiority of the bricks. The rattler test is particularly applicable to bricks used for road making (Section XIV) and for lining furnaces.

Tiles.

Roofing Tiles are made of materials similar to those used for bricks, but of a somewhat finer texture. No official specifications have been published, but it is recognised that roofing tiles should be light, tough, and ring clearly when struck, be impervious to water in the sense that even under a continuous supply of water no dripping will occur from the underside of the tile when placed at the same angle as when in use on a roof. It is desirable that tiles should be moderately porous, so as to avoid undue condensation of their underfaces.

Glazed Tiles are used partly for decorative purposes, but chiefly for sanitary reasons. The glaze should be sufficiently hard to resist all reasonable abrasion and it should not craze (forming hair-like cracks) after prolonged use. For chemical laboratories and other special purposes a felspathic glaze burned at about 1300° C. must be used in order that it may be sufficiently resistant to corrosive fluids, etc. (see 'Stoneware,' *infra*).

Paving Tiles, like paviour bricks, should be very hard and resistant to abrasion. To prevent animals slipping on them, the surface may be channelled with small grooves forming a diamond pattern.

Paving tiles are usually made of the same material and in the same manner as paving or engineering bricks.

Blocks and Terra-Cotta.

The chief requirements of *blocks* made of clay and allied materials are accuracy in shape and size, and ample strength to carry the superimposed loads. For external work, appearance is also important.

Terra-cotta is largely used in conjunction with structural steel work, the latter taking the bulk of the stresses and the terra-cotta forming a sort of filler and cover of great resistance to climatic conditions and of pleasing appearance. There is no necessity to impose any conditions as to its strength, as in a properly designed structure it would not be exposed to any severe stresses.

* The weight of the balls, the number of revolutions, and the size of the rejected pieces, differ with various engineers.

Blocks for boilers are made of special shapes. They must be sufficiently heat-resisting not to be affected by the conditions to which they are subject when in use. They must be very accurate in shape and size or there will be a serious leakage into the side flues. (Section XXIX, Part II.)

HOLLOW BLOCKS.

For many years in France and in some of the Colonies, but only recently in this country, the advantages which hollow blocks possess over building bricks have been realised. Such blocks are only one-third of the weight of the same number of bricks; they can be laid about four times as rapidly, and they are of ample strength for all purposes for which ordinary bricks are used. In addition, they automatically form a cavity wall, with all its advantages of warmth

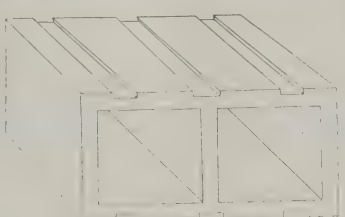

FIG. 1.

and soundproofness. Their great strength is really due to the fact that the bricks in a solid mass of brickwork have about ten times the crushing strength of the brickwork as a whole. Consequently a large proportion of the solid interior is quite useless and only adds to the cost of material, carriage, and labour; these costs are saved when hollow blocks are used.

Hollow building blocks are made in various shapes and sizes, according to the purposes for which they are to be used, and numerous patents have been granted in connection with them.

The *clays* used for making hollow blocks are the same as those employed in the manufacture of terra-cotta and roofing tiles. Such clays must vitrify sufficiently to form a strong, weather-resisting mass when fired. They must retain their shape perfectly at any temperature to which they may be exposed in the kiln, and whenever possible they should have a pleasing colour so as to avoid the necessity of 'rough casting.' Suitable clays and shales are found in various parts of the country, particularly in the Midlands. The lower grades of fireclays found in the various coalfields are also suitable, provided their buff colour is not regarded as objectionable.

The *process* of manufacture consists in preparing a clay paste of suitable consistency and extruding it through a die or mouthpiece, the interior of which is fitted with a number of cores, fig. 1, corresponding to the hollow portions of the blocks. The extruded column of clay is then cut by wires into suitable lengths, and the resulting blocks are dried and burned like bricks or architectural terra-cotta.

No standard specifications for hollow blocks have as yet been issued, but it is obvious that if the crushing strength of such blocks when they are laid in the same position as that in which they will be used, is greater than the normal strength of brickwork, such blocks will have ample strength. In most cases the blocks themselves have more than twice the strength of normal brickwork.

STONEWARE, SANITARY WARE, AND DRAIN PIPES.

Stoneware, as used by engineers, is chiefly employed in chemical works in the construction of appliances for dealing with corrosive fluids both at low and high temperatures.

The conditions under which it is used are exceptionally severe and yet are so varied that no widely acceptable specifications have been found possible. For chemical and industrial purposes, stoneware should consist of an impervious body of great crushing strength and with a minimum sensitiveness to sudden changes in temperature. The ideal is closely approached by the porcelain crucibles used in chemical laboratories, but this is too costly and too fragile for most commercial purposes and various coarser substitutes are therefore employed. To a very large extent the manufacturers of stoneware appliances may be relied upon to supply a satisfactory product if they are fully informed as to the conditions to which it will be subjected. Where troubles arise, they are often due to an engineer requiring a piece of stoneware of a design or shape which is incompatible with the nature of the material used.

Sanitary Ware is not subjected to the same conditions as stoneware, and may therefore consist of a porous body covered with a hard felspatic glaze, though an impervious body is

preferable where expense is no object. It is highly important that the glaze should be of a suitable character, earthenware and lead glazes seldom being sufficiently durable. In designing sanitary ware it is desirable to work in close co-operation with the manufacturer, as in this way much delay in production and a considerable saving in cost may be effected, and the ware is likely to be more satisfactory. As far as possible, joints and sharp arrises or corners should be avoided.

Drain Pipes are frequently made of a porous body which is covered with a salt-glaze, but for the best work a vitreous or impervious body should be used. If the glaze is defective or damaged an impervious body will maintain the efficiency of the pipes, but a porous body may permit seepage of a disagreeable or even harmful character.

For 'The British Standard Specification for Salt-Glazed Pipes' see page 1246.

ELECTRICAL WARE.

Electrical Ware is chiefly used in the form of conduits, insulators, and fittings. The conduits are usually made of coarse stoneware and are similar in many respects to salt-glazed drain pipes (*supra*).

Other electrical ware is made of fine stoneware or porcelain. Insulators must have a fine and uniform texture and their fractured surface should be free from holes and fissures; they must be able to resist the passage of electric currents of the desired voltage without appreciable leakage, and should be tested at a considerably higher voltage to ensure this.

REFRACTORY MATERIALS. *

The term '*Refractory*' is applied to various heat-resisting materials, such as firebricks, crucibles, and furnace linings. There is no official definition of this term, but it is becoming increasingly customary to regard 1580° C. (2876° F.) as a minimum temperature, materials which suffer deformation when heated rather slowly to this temperature being excluded from what are generally regarded as refractory materials.

As the rate of heating has an important influence on the temperature at which deformation occurs, it is necessary, for comparative purposes, to specify the conditions of heating.

MELTING POINTS OF REFRACTORY MATERIALS.

	°C.		°C.
Alumina (pure)	2010†	Ganister	1700 to 1800
Bauxite	1820†	Kaolin	1835 to 1740†
Bauxite brick	1565 to 1785†	Magnesia brick	2165
Bauxite clay	1795†	Silica—Pure	1750†
Chromite	2180†	Pure	1830
Chromite brick	2050†	Pure with 14·5 per cent. alumina	1690
Fireclay brick—Highest grade	1843	Pure with 63·0 per cent. alumina	1890
General grade	1680 (average)	Brick	1700 to 1750
General grade (average of 41 samples)†	1649		

The term 'melting point' is misleading when applied to refractory materials, as these are seldom, if ever, melted, and the term is generally used to indicate the temperature at which a small pyramid or 'cone' of the material bends over until its apex is on a level with its base, or, alternatively, at which the angular edges of the pyramid begin to lose their angularity.

FIREBRICKS.*

Fireclay bricks are made of clays derived chiefly from the coal measures. These clays are crushed to powder mixed with water and made into bricks either by hand-moulding or machines of the stiff-plastic or semi-dry type; the bricks are then dried and are afterwards burned in kilns. The temperature attained in burning should be at least as high as that to which the bricks will be subjected when in use, as otherwise shrinkage and other defects may occur. It is seldom that bricks burned at such high temperatures are obtained unless they are definitely specified; and for some purposes, such as lining steel-melting furnaces, users must be content with bricks fired at a lower temperature than that at which they will be employed. The highest temperature ordinarily attained in burning firebricks is about 1350° C.

Firebricks are also made of silica (in which case they are known as *Ganister* or *Silica Bricks*), alumina (*Bauxite* or *Semi-bauxite Bricks*), magnesia (*Magnesia* or *Magnesite Bricks*), chrome iron ore (*Chromite Bricks*), and graphite (*Carbon Bricks*).

---

* See also 'Refractory Materials,' by A. B. Searle (Griffin & Co., London).

† Kanolt. The temperatures are those at which the materials were first seen to flow easily.

Firebricks made of clay or silica are acid in character and are readily attacked by the limestone used as a flux in steel furnaces. *Basic Bricks* are made of magnesia, whilst *Neutral Bricks* are made of bauxite, chromite or carbon: the two latter are chiefly used as an intermediate course between acid and basic bricks in furnace linings.

Ordinary fireclays contain 58 to 75 per cent. of silica, 25 to 36 per cent. of alumina, and ½ to 2 per cent. of iron oxide. Good silica bricks contain upwards of 95 per cent. of silica, little or no alumina, and under 2 per cent. of lime. Ganister bricks contain about 90 per cent. of silica, 5 per cent. of alumina and less than 2 per cent. of iron oxide. Magnesia bricks consist almost wholly of magnesia, unless about 5 per cent. of clay or iron oxide has been used to bind the particles together.

Fireclays as used on Gasworks.

Refractory materials as employed on gasworks are in general classified in accordance with the percentage of silica which they contain. There are three distinct varieties of clay, known respectively as:

(*a*) Aluminous clays;
(*b*) Siliceous clays;
(*c*) Silica clays.

The so-called aluminous clays are those belonging to the Stourbridge varieties, which contain on an average about 65 per cent. of silica. Siliceous clays are intermediate in composition, and include those types which contain from 80 to 92 per cent. of silica, such as the well-known Ewell variety. Silica clays are those which contain above 92 per cent. of silica, such as the Dinas and Black Ganister varieties. The composition of typical fireclays is shown in the following analyses:

	Per cent.
Stourbridge Clay—	
Silica	64·62
Alumina	21·65
Ferric oxide	1·48
Lime	1·88
Magnesia	0·62
Moisture	9·62
Ewell Clay—	
Silica	87·57
Alumina	3·60
Ferric oxide	4·80
Lime	0·74
Magnesia	0·41
Potash	0·69
Soda	0·10
Water of combination	2·09
Dinas Clay—	
Silica	97·60
Alumina	0·50
Ferric oxide	1·50
Lime	0·20
Potash	0·09
Soda	0·03
Black Ganister—	
Silica	98·5
Alumina	0·3
Ferric oxide	1·3
Lime	0·2
Potash	traces
Soda	traces

The impurities in fireclays, i.e. those constituents other than the silica and alumina, have a most harmful effect on the refractoriness of the material owing to their low fusing point. These constituents should, if possible, never be allowed to exceed more than 4 to 5 per cent. Much must, of course, depend upon the type of clay, and it is possible to point to certain substances containing so much as 4 per cent. of iron alone, and yet they are highly refractory. Green clay when fired is subject to considerable shrinkage, and it is for this reason that chamotte, or 'grog,' is added in varying proportions before the article is placed in the kiln. This 'grog' is usually prepared from a clay which originated in the same seam as the clay with which it is mixed. It should be prepared specially for the purpose, and should not consist of the crushings from defective and broken articles which have passed through the kiln. The quantity of 'grog' added varies, of course, with the material required and the kind of clay made use of. For firebricks and smaller articles it is usually added in a proportion of 15 to 20 per cent. For larger articles, such as retorts, the amount is increased to 30 to 40 per cent. (*Alwyne Meade.*)

The deformation or softening points of firebricks vary considerably. The following are fairly typical :—

Fireclay bricks, 1610–1770°C. ; Silica bricks, 1670–1790°C. ; Magnesia bricks, 1730–2000°C.

Specification for Fireclay Bricks.

The following paragraphs contain the salient features of the Specifications for Firebricks issued by the Institution of Gas Engineers (1911, revised 1912).

(1) *Refractoriness.*—Two grades of material are covered by the specification :—

(*i*) The material which shows no sign of fusion when heated to a temperature of not less than Seger Cone 30 (about 1670°C.).

(*ii*) Material which shows no sign of fusion when heated to a temperature of not less than Seger Cone 26 (about 1580°C.).

(2) *Surfaces and Texture.*—The material shall be evenly burnt throughout and the texture regular, containing no holes or flaws. All surfaces shall be reasonably true and free from flaws or winding.

(3) *Contraction or Expansion.*—A test piece, when heated to a temperature of Seger Cone 14 for two hours, shall not show more than the following linear contraction or expansion :—

No. 1 grade, 1 per cent. ; No. 2 grade, 1·25 per cent.

After the test temperature has been reached, the furnace shall be maintained constant at that temperature throughout the testing period.

The test piece shall be 4½ inches long and 4½ inches wide, the ends being ground flat, and the contraction being measured by means of vernier calipers reading to 0·1 mm., a suitable mark being made on the test piece, so that the calipers may be placed in the same position before and after firing.

(4) *Variations from Specified Measurements.*—In the case of ordinary bricks, 9 inches by 4½ inches by 3 inches or 2½ inches thick, there shall not be more than ± 1½ per cent. variation in length, nor more than ± 2½ per cent. variation in width or thickness, and in all cases the bricks shall work out their own bond, with not more than ⅛ inch allowance for joint. In the case of special bricks, blocks or tiles, there shall not be more than ± 2 per cent. variation from any of the specified dimensions.

(5) *Crushing Strength.*—The material shall be capable of withstanding a crushing strain of not less than 1,800 lbs. per square inch when applied to whole bricks placed with their long side vertical between the jaws of the machine, giving a vertical thrust.

Specification for Silica Bricks.

(Institution of Gas Engineers, 1912.)

The material covered by this specification is divided into two classes :—

(*i*) That containing 92 per cent. and upwards of silica, and hereinafter called 'silica' material.

(*ii*) That containing from 80 to 92 per cent. of silica, and hereinafter called 'siliceous.'

(1) *Refractoriness.*—Test pieces of the material shall show no sign of fusion when heated to the following temperatures :—

'Silica' material not less than Seger Cone 32 (about 1710°C.).

'Siliceous' material not less than Seger Cone 29 (about 1650°C.)

The test shall be carried out in an oxidising atmosphere, the temperature of the furnace being increased at the rate of about 50°C. per five minutes.

(2) *Surface and Texture.*—The material should be evenly burned throughout, and the texture regular, with no holes or flaws. All surfaces shall be reasonably true and free from flaws or winding.

(3) *Contraction and Expansion.*—A test piece, when heated in a gas muffle or electric furnace to a temperature of Seger Cone 14 for two hours, shall not show on cooling more than 0·75 per cent. linear contraction or expansion. The test piece shall be at least 4½ inches long by 4½ inches wide, the ends being ground flat, and the contraction or expansion measured by means of vernier calipers reading to 0·1 mm., a suitable mark being made on the test piece, so that the calipers may be placed in the same position before and after firing. The test samples shall not be taken out of the middle of a brick or tile, but shall be representative of the whole.

(4) *Variations from Measurements.*—In the case of ordinary bricks, 9 inches by 4½ inches by 3 inches or 2½ inches thick, there shall not be more than ± 1½ per cent. variation in length, nor more than ± 2½ per cent. variation in width or thickness ; and in all cases the bricks shall work out their own bond. Special bricks, blocks, or tiles shall not have more than ± 2 per cent. variation from any of the specified dimensions.

Specifications for Refractory Mortar or Cement

(Institution of Gas Engineers, 1911; revised 1912.)

Cementing clay or fireclay mortar shall be machine-ground, and, at the discretion of the manufacturer, may contain a suitable percentage of fine grog; but in all cases the cement-clay shall be quite suitable for the purpose of binding together the bricks, blocks or tiles for which it is supplied, and shall be capable of withstanding the same test for refractoriness.

This specification applies equally to cement or mortar used for bricks made of either fireclay or silica.

BRICKS OR BLOCKS FOR FURNACE LININGS.

The bricks or blocks used for lining furnaces should be selected according to the conditions to which they will be subjected. It is almost impossible to obtain a material which is wholly efficient in every respect, and some compromise is essential. Thus, great resistance to abrasion can only be obtained by increasing the amount of vitreous material and thereby lowering the refractoriness of the bricks. Answers to the following questions will usually provide most of the information required :—

(*a*) What is the highest temperature to which the brick will be exposed (excessive or only moderate), and will it be constant or fluctuating? (*b*) Will the material come into contact with any flame, and will the latter be of an 'oxidising' or 'reducing' character? (*c*) Is mechanical strength required? (*d*) Is heat to be conducted or retained? (*e*) Is the brick expected to withstand sudden and repeated changes in temperature? (*f*) Will the brick come into contact with fluid slags or glass, or with flue-dust, cement or other fluxes? (*g*) Must the brick resist blows, shocks and other unavoidable strains? (*h*) What is the nature of the fuel used and is it fed by hand or mechanically? (*i*) Is the electrical conductivity important?

To meet (*a*), refractoriness is of much importance, but, in most cases, other factors deserve even greater attention. For (*b*) and (*c*) the texture of the surface of the brick must be right or the brick will not be durable, no matter how great its refractoriness. If mechanical strength is needed, the brick cannot be as refractory as otherwise, for great strength is dependent on the presence of a large amount of bond, which is necessarily less refractory than the particles to be bound together. For (*d*), it will be found that the conduction of heat depends chiefly on the density of the material If made of clay or silica and on its chemical composition if made of graphite, plumbago or other carbonaceous material. Graphite, fused alumina and zirconia are good heat conductors, whilst clay, silica and magnesia are good heat retainers. For (*e*) a lean, coarse and porous material should be used whilst for (*f*) a fat, close material is required, i.e. exactly opposite to that for (*e*), and for (*g*) a hard-burned material which has not been heated more than once is preferable; broken bricks and other refractory articles should not be used as grog in this case, and the mass should not be either too lean or too fine-grained.

Consideration of the above points will show that there is some difficulty in deciding upon the correct description of the material for use in the ordinary type of industrial furnace. Where bricks of high refractoriness are required to withstand the temperature employed, heat must be retained and radiation reduced to a minimum, though most of these requirements are satisfied by using an open-grained, porous material. Still greater difficulty arises in dealing with furnaces in which fluxes are brought into contact with the firebricks, and in these the material must be close-grained, even if this is accompanied by the loss of some heat resistance.

Where great resistance to fluxes (flue-dust, lime and other bases) is required, the refractoriness of the brick is of secondary importance to the closeness of texture. Under such conditions, a porous, highly refractory brick will be far less durable than a dense brick of much lower fusing point. The fluxes act less rapidly on a comparatively smooth, dense surface than on a more porous one, so that the 'life' of the former brick will be longer than the latter, notwithstanding the fact that its actual heat resistance may be lower. For this reason, many fireclays which are of No. 2 quality as regards heat resistance are preferable for use in some furnaces and for flue work generally.

In some heating appliances, the draught and the atmosphere to which the refractory material is exposed have a far greater influence on the durability of the latter than is generally supposed. Unless properly managed, such furnaces may cause firebricks to be destroyed in a few weeks, whereas under proper conditions of draught they would last almost as many years. This is a matter of which firebrick manufacturers have no special knowledge and most builders and users of furnaces are equally ignorant. It is, in fact, one which can only be properly investigated by a specialist in refractory materials.

RAMMED FURNACE LININGS.

Furnaces are sometimes lined with a stiff paste which is rammed into position. The composition of such rammed linings varies with the purpose for which the furnace is used; a well known material consists of ganister to which a little lime has been added and the mixture then made into a very stiff paste with water.

Various kinds of sand, with or without sufficient clay or other binding agent to make the mass adhesive, are largely used for lining and repairing furnaces. (See also 'Refractory Cements,' p. 431.)

GAS RETORTS.

The chief forms of gas retorts are briefly described in Section XXXIV. They are usually made of a mixture of fireclay and 'grog,' the latter consisting of fireclay which has previously been burned and reduced to a very coarse powder. The grog should not consist of particles of uniform size, but should be graded so as to produce a material capable of withstanding sudden changes in temperature. The proportions of grog and clay must be adapted to the nature of the clay and the size and shape of the retort. The retorts require to be dried very slowly and carefully, and to be burned at a sufficiently high temperature to prevent them shrinking unduly when in use.

The following paragraphs contain the salient features of the Specification for Gas Retorts issued by the Institution of Gas Engineers in 1911, revised 1912.

SPECIFICATION FOR GAS RETORTS.

(Institution of Gas Engineers, 1911; revised 1912.)

(1) *Constituents.*—The retorts or retort tiles shall be made of sufficiently seasoned raw clay and clean-burnt 'grog.' No 'grog' shall be used which will pass through a test sieve having 16 meshes to the linear inch.

Standard sieves* to be used.

(2) *Refractoriness.*—A piece of the material shall show no signs of fusion when heated to a temperature not less than Seger Cone 28 (about 1630°C.), the heat being increased at a rate of about 50°C. per five minutes in an oxidising atmosphere.

The material is to be chipped to the form and size of a Seger Cone, and tested against standard Seger Cones (small size).

(3) *Surfaces and Texture.*—All surfaces shall be reasonably true and free from flaws or winding, and after burning no 'washing' shall be done without the consent of the engineer (or purchaser). The texture throughout shall be even and regular, containing no holes or flaws, and the 'apparent porosity' shall not be less than 18 per cent. by volume.

(4) *Contraction.*—The material shall be evenly burnt throughout and contain no black core. A test piece, when heated to a temperature of Seger Cone 14 for two hours, shall not show, when cold, more than 1¼ per cent. contraction or expansion. The test piece shall be 4½ inches by 1½ inches, the ends being ground flat, and the contraction being measured by means of vernier calipers, reading to 0·1 mm., a suitable mark being made on the test piece, so that the calipers may be placed in the same position before and after firing.

Retorts made of *silica bricks and blocks* have, in recent years, achieved great success, as they transmit the heat better than fireclay. For these the Specification for Silica Bricks (p. 428) is suitable.

CRUCIBLES.

Crucibles are made of (*i*) fireclay to which a suitable proportion of sand has been added, (*ii*) graphite or plumbago with a sufficient amount of clay or other binder, and (*iii*) various other materials of a special character such as magnesia, zirconia, etc. Crucibles must be sufficiently refractory to withstand the heat to which they are subjected, and whilst at the highest temperature at which they are used they must be sufficiently strong to be lifted out of the furnace, with their contents. Equally important is the resistance offered to the action of their contents, and as no crucible is equally suitable for all purposes careful selection is necessary.

A common test for the ability of a crucible to withstand corrosion is to half fill it with copper and to add a little borax. As the copper melts, part of it will be oxidised, the borax will absorb the oxide and will rapidly corrode the crucible, unless the latter is of excellent quality.

Another useful test consists in melting red lead and copper oxide in the crucible to be tested. Most crucibles will be perforated by the fused mixture after a few minutes' heating, but a satisfactory crucible will stand prolonged heating.

Silica is more readily corroded than clay or grog, but graphite is not affected at all. Hence, for highly corrosive contents, grog or graphite crucibles and not siliceous ones should be used.

Resistance to sudden changes in temperature is an essential property of a good crucible. How necessary is this resistance may be realised from the fact that a crucible may be withdrawn from a furnace at 1800°C., with its contents of 80 lbs. of steel at 1500°C. The steel is at once poured out and replaced by air at a temperature of only 20°C. Yet, notwithstanding the severity of

* It is necessary to observe that in the standard 16-mesh sieve the wires and spaces are of equal diameter, so that such a sieve only allows pieces less than $\frac{1}{32}$ inch linear dimension to pass through it. Sieves with spaces and wires of any other dimensions will not give results in conformity with the specification.

such conditions, crucibles are regularly used for this purpose. On the other hand, many clay crucibles which have been used once and allowed to become cold cannot be used again, as they crack when reheated.

Further information will be found in ' Refractory Materials ' by A. B. Searle (Griffin & Co., London).

ABRASIVE WHEELS AND BLOCKS.

The vitrified bonds used in the manufacture of some abrasive wheels, blocks, etc., are largely composed of clay. For further details see Section XX, Part II, p. 1003–1019.

HEAT-INSULATING MATERIALS.

Materials used for retaining the heat inside pipes, cylinders, etc., are largely made of clay of allied materials, the most important ingredients being kieselguhr, magnesia, brick dust, felt, and various fibrous materials (see p. 1437).

CEMENTS.

Many cements are clay products of a more or less definite character. Thus, *Portland cement* is made by heating a carefully proportioned mixture of clay and limestone or chalk until they combine and the mass sinters. *Roman cement* and hydraulic lime are crude materials of the same character in which a natural material is used containing the clay and lime compounds in suitable proportions (see p. 395).

FIRE-RESISTING OR REFRACTORY CEMENTS.

These cements—usually sold under a fancy name are used for patching furnaces, and other appliances subjected to heat. The precise nature of most of these cements is regarded as a trade secret, but many of them are composed of fireclay, ground firebricks, and Portland cement or water-glass. These materials, when properly selected and mixed in the proper proportions, form a paste which adheres readily to cold brickwork, and when the latter is heated the nature of the cement is changed and a strong heat-resisting material is produced.

The commonest cements for use with various bricks consists of a slip made from the same material as that of the bricks. Thus, a mixture of fireclay and brick-dust (grog) is used with fireclay bricks, whilst a mixture of sand and sodium silicate is often used for bonding silica bricks.

Ground ganister or a mixture of silica rock and fireclay is largely used for lining furnaces (see foot of p. 429).

Special cements are used in certain cases ; fused alumina and carborundum cements are sometimes used in retorts and muffles, a small proportion of clay being used as a bonding agent. Powdered zirconia, ground so as to pass through a 200-mesh sieve, is very effective at exceptionally high temperatures, whilst other special mixtures may also be employed where a mixture of unusual composition is needed.

SECTION X

REINFORCED CONCRETE CONSTRUCTION.

(Contributed by Alexander Drew, M.I.Mech.E., M.C.I.)

REPORT OF JOINT COMMITTEE OF ROYAL INSTITUTE OF BRITISH ARCHITECTS.*

(*Abstract.*)

Good workmanship and materials are essential in reinforced concrete.

It is essential that the workmen employed should be skilled in this class of construction.

Very careful superintendence is required during the execution of the work in regard to—

(*a*) The quality, testing, and mixing of the materials.

(*b*) The sizes and positions of the reinforcements.

(*c*) The construction and removal of centering.

(*d*) The laying of the material in place, and the thorough punning of the concrete to ensure solidity and freedom from voids.

If the metal skeleton is properly coated with cement, and the concrete is solid and free from voids, there is no reason to fear decay of the reinforcement in concrete of stone, gravel, cinder, coke-breeze, etc., made with clean, fresh water.

Fire Resistance.

Experiment and actual experience of fires show that concrete in which limestone is used for the aggregate is disintegrated, crumbles and loses coherence when subjected to very fierce fires, and that concretes of gravel or sandstones also suffer, but in a rather less degree. The metal reinforcement in such cases generally retains the mass in position, but the strength of the part is so much diminished that it must be renewed. Concrete in which coke-breeze, cinders, or slag forms the aggregate is only superficially injured, does not lose its strength, and in general may be repaired. Concrete of broken brick suffers more than cinder concrete and less than gravel or stone concrete.

Rigidly attached web members, loose stirrups, bent-up rods, or similar means of connecting the metal in the lower or tension sides of beams or floor slabs (which sides suffer most injury in case of fire) with the upper or compression sides of beams or slabs not usually injured are very desirable.

In all ordinary cases a cover of $\frac{1}{2}$ inch on slabs and 1 inch on beams is sufficient. It is undesirable to make the covering thicker. All angles should be rounded or splayed to prevent spalling off under heat.

More perfect protection to the structure is required under very high temperature, and in the most severe conditions it is desirable to cover the concrete structure with fire-resisting plastering which may be easily renewed. Columns may be covered with coke-breeze concrete, terra-cotta, or other fire-resisting facing.

Materials.

Cement.—Only Portland cement complying with the requirements of the specification adopted by the British Engineering Standards Committee should be employed; in general the slow-setting quality should be used.

Sand.—The sand should be composed of hard grains of various sizes up to particles which will pass a $\frac{1}{4}$-inch square mesh, but of which at least 75 per cent. should pass $\frac{1}{8}$-inch square mesh.

* By permission.

R.I.B.A. JOINT COMMITTEE'S REPORT—*continued.*

Fine sand alone is not so suitable, but the finer the sand the greater is the quantity of cement required for equal strength of mortar. It should be clean and free from ligneous, organic, or earthy matter.

Aggregate.—The aggregate, consisting of gravel, hard stone, or other suitable material,* should be clean and angular, varied in size as much as possible between the limits of size allowed for the work. In all cases material which passes a sieve of $\frac{1}{4}$-inch square mesh should be reckoned as sand. The maximum allowable size is usually $\frac{3}{4}$ inch. The maximum limit must always be such that the aggregate can pass between the reinforcing bars and between these and the centering. The sand should be separated from the gravel or broken stone by screening before the materials are measured.

Proportions of the Concrete.—For ordinary work a proportion of 1 part cement to 2 parts sand will be found to give a strong, practically watertight mortar, but where special watertightness or strength is required the proportion of cement must be increased.

The weight of a cubic foot of cement for the purpose of proportioning the amount of cement to be added may be taken at 90 lbs.

Metal.—The metal used should be steel having the following qualities :—

(*a*) An ultimate strength of not less than 60,000 lbs. per square inch.

(*b*) A yield point of not less than 32,000 lbs. per square inch.

(*c*) It must stand bending cold 180° to a diameter of the thickness of pieces tested without fracture on outside of bent portion.

(*d*) In the case of round bars the elongation should not be less than 22 per cent., measured on a gauge-length of eight diameters. In the case of bars over one inch in diameter the elongation may be measured on a gauge-length of four diameters, and should then be not less than 27 per cent.

For other sectional material the tensile and elongation tests should be those prescribed in the British Standard Specification for Structural Steel. If hard or special steel is used, it must be on the architect's or engineer's responsibility and to his specification.

Before use in the work the metal must be clean and free from scale or loose rust. It should not be oiled or painted.

Welding should in general be forbidden ; if it is found necessary, it should be at points where the metal is least stressed, and it should never be allowed without the special sanction of the architect or engineer responsible for the design.

The reinforcement ought to be placed and kept exactly in the positions marked on the drawings, and, apart from any consideration of fire resistance, ought not to be nearer the surface of the concrete at any point than 1 in. in beams and pillars, and $\frac{1}{2}$ in. in floor slabs or other thin structures.

Mixing.—When the materials are mixed by hand they are to be turned over and thoroughly mixed on a clean platform until the colour of the cement is uniformly distributed over the aggregate. Whenever practicable the concrete should be mixed by machinery.

Laying.—The thickness of loose concrete that is to be punned should not exceed 3 ins. before punning, especially in the vicinity of the reinforcing metal. Special care is to be taken to ensure perfect contact between the concrete and the reinforcement, and the punning is to be continued till the concrete is thoroughly consolidated. Each section of concreting should be as far as possible completed in one operation† ; when this is impracticable, and work has to be recommenced on a recently laid surface, it is necessary to wet the surface ; and where it has hardened it must be hacked off, swept clean, and covered with a layer of cement mortar $\frac{1}{2}$ in. thick, composed of equal parts of cement and sand. Work should not be carried on when the temperature is below 34° Fahr. The concrete when laid should be protected from the action of frost, and shielded against too rapid drying from exposure to the sun's rays or winds, and kept well wetted. All shaking and jarring must be avoided after setting has begun. The efficiency of the structure depends chiefly on the care with which the laying is done.

Centering or Casing.—The centering must be of such dimensions, and so constructed, as to remain rigid and unyielding during the laying and punning of the concrete. It must be so arranged as to permit of easing and removal without jarring the concrete. Provision should be made wherever practicable for splaying or rounding the angles of the concrete. Timber when used for centering may be advantageously limewashed before the concrete is deposited.

---

* Coke-breeze, pan-breeze or boiler-ashes ought not to be used for reinforced concrete. It is advisable not to use clinker or slag, unless the material is selected with great care.

† In particular the full thickness of floor slab should be laid in one operation.

R.I.B.A. JOINT COMMITTEE'S REPORT—*continued.*

Striking of Centres.—The casing for columns, for the sides of beams, and for the soffits of floor slabs not more than 4 ft. span must not be removed under eight days; soffits of beams and of floors of greater span should remain up for at least fourteen days, and for large span arches for at least twenty-eight days.

Testing.—In the case of concrete made in proportions of 1 cement, 2 sand, 4 hard stone, the strength should not be less than 1,800 lbs. per square inch in compression after 28 days.

Loading tests on the structure itself should not be made until at least two months have elapsed since the laying of the concrete. The test load should not exceed one and a half times the accidental load. Consideration must also be given to the action of the adjoining parts of the structure in cases of partial loading. In no case should any test load be allowed which would cause the stress in any part of the reinforcement to exceed two-thirds of that at which the steel reaches its elastic limit.

Methods of Calculation.

DATA.

Loads.—The weight of the concrete and steel structure may be taken at 150 lbs. per cubic foot.

In structures subjected to very varying loads and more or less vibration and shock, as, for instance, the floors of public halls, factories, or workshops, the allowance for shock may be taken equal to half the accidental load. In structures subjected to considerable vibration and shock, such as floors carrying machinery, the roofs of vaults under passage ways and courtyards, the allowance for shock may be taken equal to the accidental load.

In the case of columns or piers in buildings, which support three or more floors, the load at different levels may be estimated in this way:—For the part of the roof or top floor supported, the full accidental load assumed for the floor and roof is to be taken. For the next floor below the top floor 10 per cent. less than the accidental load assumed for that floor. For the next floor 20 per cent. less, and so on to the floor at which the reduction amounts to 50 per cent. of the assumed load on the floor. For all lower floors the accidental load on the columns may be taken at 50 per cent. of the loads assumed in calculating those floors.

In the case of many warehouses and buildings containing heavy machinery it is desirable not to make any reduction of the actual loads.

Stresses in Beams.

(*a*) The coefficient of elasticity in compression of stone or gravel concrete, not weaker than 1 : 2 : 4, is treated as constant and taken at one-fifteenth of the coefficient of elasticity of steel.

	Lbs. per Sq. In.
Coefficient for concrete = E_c =	2,000,000
,, steel = E_s =	30,000,000

$$\frac{E_s}{E_c} = 15.$$

It follows that at any given distance from the neutral axis, the stress per square inch on steel will be fifteen times as great as on concrete.

(*b*) The resistance of concrete to tension is neglected, and the steel reinforcement is assumed to carry all the tension.

(*c*) The stress on the steel reinforcement is taken as uniform on a cross-section, and that on the concrete as uniformly varying.

Working Stresses.

If the concrete is of such a quality that its crushing strength is 1,800 lbs. per square inch after twenty-eight days, and the steel has a tenacity of not less than 60,000 lbs. per square inch, the following stresses may be allowed:—

	Lbs. per Sq. In.
Concrete in compression in beams subjected to bending	600
Concrete in columns under simple compression	600
Concrete in shear in beams	60
Adhesion * of concrete to metal	100
Steel in tension	16,000
Steel in shear	12,000
Steel in compression	15 times the stress in the surrounding concrete

* It is desirable that the reinforcing rods should be so designed that the adhesion is sufficient to resist the shear between the metal and concrete. Precautions should in every case be taken by splitting or bending the rod ends, or otherwise to provide additional security against the sliding of the rods in the concrete.

R.I.B.A. JOINT COMMITTEE'S REPORT—*continued.*

When the proportions of the concrete differ from those stated above, the stress allowed in compression on the concrete may be taken at one-third the crushing stress of the cubes at twenty-eight days as determined above.

If stronger steel is used, the allowable tensile stress may be taken at one-half the stress at the yield point of the steel, but in no case should it exceed 20,000 lbs. per square inch.

Beams of Rectangular and T Section.

In the calculation of all beams the area upon which the ratio of tensile reinforcement is taken is considered as a rectangle of breadth equal to the greatest breadth of the beam and of depth equal to the greatest effective depth of the beam.

In designing beams where the rib is monolithic with a slab, the beam may be considered to be of T form. The slab must first be calculated and designed, having its own reinforcing bars transverse to the rib. The whole of the slab cannot in general be considered to form part of the upper flange of the T beams. The width b_1 of the upper flange may be assumed to be not greater than one-third the span of the beams, or more than three-fourths of the distance from centre to centre of the reinforcing ribs or more than fifteen times the thickness of slab. The width b_r of the rib should not be less than one-sixth of the width b_1 of the flange.

Shear Reinforcement.

It is always desirable to provide reinforcement to resist the shearing and diagonal tension stresses in reinforced concrete beams. The diagonal tension stresses depend on the vertical and horizontal shear and also on the longitudinal tension at the point considered. As the longitudinal tension in the concrete at any given point is very uncertain, the amount and direction of the diagonal tension cannot be exactly determined.

It is the general practice to determine the necessary reinforcement by taking the vertical and horizontal shearing only into consideration.

Experience shows that:

(*a*) In general, floor slabs require no special reinforcement against shearing and that the bending up of alternate bars near the end is sufficient.

(*b*) In beams, especially in T beams, shearing reinforcement should be provided at distances apart not exceeding the depth of the beam.

(*c*) It is desirable to bend up one or more of the bars of the tension reinforcement near the supports. When bent at an angle of about 45° the effect of this may be taken into account in the manner set out above; when bent at a small angle to the horizontal the effect is very indeterminate.

(*d*) As the resistance of the shear members to the pull depends on the adhesion, and the anchorage at the ends, it is desirable to use bars of small diameter, and to anchor the stirrups at both their ends. In all cases the stirrups must be taken well beyond the centre of compression.

Slabs Supported or Fixed on more than Two Sides.

It does not appear that there is either a satisfactory theory or trustworthy experiment from which the strength of rectangular slabs supported or fixed on all four edges can be determined.

Pillars and Pieces under Direct Thrust.

DEFINITIONS.

The length is to be measured between lateral supports (neglecting ordinary bracketing).

The effective diameter of a pillar means the least width and should be measured to the outside of the outermost vertical reinforcement.

The effective area of a pillar means the area contained by the outermost lateral reinforcement, and should be measured to the outside of the outermost vertical reinforcement.

Loading and Length of Pillars.

If the load is strictly axial the stress is uniform on all cross-sections.

Lateral bending of the pillar as a whole is not to be feared, provided—

(*a*) That the ratio of length to least outside diameter does not exceed 18.

(*b*) That the stress on the concrete does not exceed the permissible working stress for the given pillar.

(*c*) That the load be central.

(*d*) That the pillar be laterally supported at the top and base.

Construction.

Lateral reinforcement properly disposed raises the ultimate strength and increases the security against sudden failure, by preventing the lateral expansion of the concrete and the sudden disruption of the pillar.

R.I.B.A. JOINT COMMITTEE'S REPORT—*continued.*

Practical considerations lead to the addition of longitudinal bars, and the formation of an enveloping network of steel.

The total cross-sectional area of the vertical reinforcement should never be less than 0·8 per cent. of the area of the hooped core.

There should be at least six vertical bars when curvilinear laterals are used, and four for square pillars having rectilinear laterals.

In the case of rectangular pillars in which the ratio between the greater and the lesser width (measured to the outside of the vertical bars) exceeds one and a half, the cross-section of the pillars should be subdivided by cross ties; and the number of vertical bars should be such that the distance between the vertical bars along the longer side of the rectangle should not exceed the distance between the bars along the shorter side of the rectangle.

The most efficient disposition of the lateral reinforcement would appear to be in the form of a cylindrical helix, the pitch or distance between the coils being small enough to resist the lateral expansion of the concrete.

Jointed circular hoops as ordinarily made are apparently not quite so efficient.

Rectilinear ties are still less adapted to resist the lateral or radial expansion of a highly stressed core.

The volume of curvilinear laterals should never be less than 0·5 per cent. of the volume of hooped core.

The diameter of rectilinear laterals should not be less than $\frac{3}{16}$ inch.

Pillars Eccentrically Loaded.

If a pillar, initially straight, is loaded eccentrically, as when a beam rests on a bracket attached to the pillar, it may be regarded as fixed at the base and free at the loaded end.

It is desirable in pillars that there should be no tension, and generally when the vertical load is considerable there is none. Cases in which the eccentricity is so great that there is tension must be treated by the methods applicable to beams if it is made a condition that the steel carries all the tension.

Long Pillars Axially Loaded.

For columns more than 18 diameters in length there is risk of lateral buckling of the column as a whole. The strength of such pillars would be best calculated by the Gordon-Rankine formulæ.

LONDON COUNTY COUNCIL (GENERAL POWERS) ACT, 1909.

REINFORCED CONCRETE REGULATIONS—(MADE JULY 1915).*

The following brief summary is intended merely to indicate the scope, and give the principal approved data.

Nothing in these Regulations interferes with the application of the formulæ, etc., for the designing of reinforced concrete structures given in the following pages.

Part I. defines reinforced concrete and indicates the application of the same to buildings whose skeleton framework, together with any party walls, is capable of safely and independently sustaining the whole of the dead and superimposed loads.

Floors, main stairs, and landings must be of incombustible material; internal stairs and landings may be of fire-resisting materials; and roofs may be of wood framing, boards, and battens.

No part of the reinforcing metal is to be used for conducting electrical currents.

Notices to be served on, and plans and calculations to be provided to the District Surveyor are detailed.

---

* Where fuller information is desired, the complete Regulations should be referred to. A reprint of the Regulations, with useful notes, illustrations, and worked examples, has been published by B. T. Batsford, Ltd., 94 High Holborn, London (price 3*s.* net).

Part II.—Superimposed Loads.

On Floors: Equivalent dead loads.

For a floor intended to be used for the purpose of	Equiv. dead load in lbs. per sq. ft.	For a floor intended to be used for the purpose of	Equiv. dead load in lbs. per sq. ft.
Domestic buildings not hereinafter specified	70	Music halls	112
Other similar purposes		Public assembly	
Asylum wards		Public concert rooms	
Common lodging-house bedrooms		Public library reading rooms	
Hospital wards	84	Retail shops	
Hotel bedrooms		Theatres	
Workhouse wards		Workshops	
Other similar purposes		Other similar purposes	
Counting houses	100	Ball rooms	150
Offices		Drill rooms	
Other similar purposes		Other similar purposes	
Art galleries	112	Similar floors subject to vibration	
Chapels		Book stores at libraries	
Churches		Museums	
Classrooms in school buildings, not being dwelling houses so used		For every floor in a building of the warehouse class, except such floors as are intended to be used for any of the purposes aforesaid—not less than	224
Lecture rooms			
Meeting rooms			

On Stairs and Landings: Minimum to be equal to a distributed dead load of 120 lbs. per square foot, but each step must be capable of safely supporting a concentrated load of 300 lbs. at any point.

On **Roofs** of greater upward inclination than 20° with the horizontal, a superimposed load (including wind pressure and weight of ice) of ' 28 lbs. per square foot of sloping surface, normal to such sloping surface, on either side of such roof.' On all other roofs, ' 56 lbs. per square foot measured on a horizontal plane.'

On floors, stairs, landings, or roofs, other than those indicated, the actual superimposed load must be provided for, ' with an equivalent margin of safety.'

For **Rolling Loads** actuated by mechanical power, take an equivalent static load equal to 1½ times the actual rolling load and provide for the stresses due to every position of such load.

Partitions and other Structures on floors or roofs whose weight exceeds the superimposed load must be specially provided for.

For calculating the **Resistance Moment**, the angle of dispersion of a point load through hard filling and concrete may be taken at not more than 45° from the vertical.

For **Buildings of more than two storeys in height** the loads on foundations, pillars, and walls may be reduced, as in Steel Regulations (para. 19, page 382).

Wind Pressure to be equal to a static horizontal pressure of not less than 20 lbs. per square foot of the whole projected surface normal to the wind direction. On **panels of external walls** allow for not less than 30 lbs. per square foot ' assumed as acting uniformly over the area of one panel from either side.'

For **all structures or attachments to buildings** (including towers or other parts extending above the roof, etc.), allow for not less than 40 lbs. per square foot of whole projected surface normal to direction of every wind.

Weight of Reinforced Concrete to be taken at not less than 144 lbs. per cubic foot measured over finished surfaces.

The **span of a beam** shall not be greater than twenty times its effective depth, unless the maximum tensile or compression stresses are correspondingly reduced below the maximum stresses recognised in these regulations.

The **length of a Cantilever** shall not exceed five times its effective depth at the bearing.

Bending Moments.—For the purpose of calculation the effective span of a beam or slab shall be taken as the clear span plus the effective depth, or the span to centres of bearings whichever is the lesser.

The values for the **bending moments due to various loadings** may be obtained graphically by means of the diagrams on pp. 292, 293, except for type loading (h), where these

regulations call for equal maximum moments at centre and at ends (to obtain the former by diagram, make value of $A=\frac{1}{6}\ Wl$).]

For Continuous Beams or Slabs the maximum positive and negative bending moments in each span may be calculated for all necessary arrangements of loading to same and to adjoining spans. Or the approximate maximum bending moments may be taken as follows :— Near middle of end span, at support next to end support, and at other interior supports, $=\frac{1}{10}$ total load × effective span ; at middle of interior spans, $=\frac{1}{12}$ total load × effective span.

For Slabs reinforced with mesh reinforcement, or reinforced in two directions at right angles to each other, the bending moments in each direction may be obtained from the table on page 455 (Reinforced Concrete Construction Section), the accepted values being those marked 'Grasnof and Rankine.'

For all loadings other than those indicated, the actual bending moments shall be calculated 'so as to give an equivalent margin of safety.'

The permissible working stresses in concrete, except as further provided for in pillars, shall not exceed the following :—

Stresses in Concrete.	Proportion by Volume.											
	Cement.	Sand.	Coarse Material.	Cement.	Sand.	Coarse Material.	Cement.	Sand.	Coarse Material.	Cement.	Sand.	Coarse Material.
	1	2	4	1·2	2	4	1·5	2	4	2	2	4
	V=6			V=5			V=4			V=3		
	Lbs. per Sq. In.			Lbs. per Sq. In.			Lbs. per Sq. In.			Lbs. per Sq. In.		
Direct compressive stress.	600			650			700			750		
Extreme flexural compressive stress in beams .	600			650			700			750		
Shearing stress . . .	60			65			70			75		
Grip or adhesion between concrete and steel bars hooked at both ends .	100			100			100			100		
Grip or adhesion between concrete and steel bars otherwise effectively anchored at the ends .	60			60			60			60		
Tensile stress	Nil			Nil			Nil			Nil		

If V is less than 3 the stresses in the last column shall not be exceeded.

The permissible working stress in steel shall not exceed the following :—

Stress in mild steel complying with the British Standards Specification . . .	Pounds per square inch.
Compressive stress	m times the stress in the concrete immediately surrounding the steel.
Tensile stress	16,000.

Eccentric loading stresses must be provided for.

For Hooks or Anchors to ends of tensile and shear reinforcement, and for **Grip Lengths**, refer to Regulations.

The elastic modulus of steel in tension or compression shall be taken at 30,000,000 lbs. per square inch.

The modular ratio for steel and concrete shall be taken as follows :—

For beams . . . . . $mc=9{,}000$ or $m=\frac{9{,}000}{c}$

For pillars with the minimum of hooping or binding . $mc=9{,}000$ or $m=\frac{9{,}000}{c}$

For pillars with more than the minimum of hooping or binding . . . . . $mi = 9{,}000$ or $m = \frac{9{,}000}{i}$

Where c = permissible *compressive* working stress given in preceding table;
i = *increased* stress allowed in pillars with more than the minimum of hooping or binding (see PART IV.).

Part III

The term 'beam' shall include any beam, girder, lintel, bressummer, or cantilever, or any other similar member carrying transverse loads.

Longitudinal bars must be at least $\frac{1}{4}$ inch in diameter, **all other reinforcing bars** being not less than $\frac{1}{4}$ inch in diameter.

Distance apart of bars at least 1 inch horizontally and $\frac{1}{2}$ inch vertically, except at joints or crossings of bars.

Tensile reinforcement to be not more than 6 inches apart.

Compression reinforcement must not be stressed to more than m times the stress in the immediately surrounding concrete, and be anchored by bars extending through a depth at least equal to the resistance moment arm, and spaced not further apart than this resistance moment arm or than sixteen times the least diameter of the anchored bar.

Where all compression stress is taken by steel rods, these may be stressed to 16,000 lbs. per square inch, and be anchored laterally and vertically not further apart than 6 inches or than eight times the diameter of the anchored bars; the anchors to be passed round or hooked over both the compressive and the tensile reinforcement.

If **hooping** is adopted, the compression stress for $\frac{1}{4}$ span from each end may be taken as that for the core of a similarly hooped pillar; the concrete outside the hooping must not be taken into account.

Shear and Web Reinforcement.—Regulations are provided as to the value of concrete alone, and with the addition of rods; and as to spacing, and anchoring of shear rods to the main reinforcing bars, etc.

Splays at ends of beams intended to increase the resistance moment must not be calculated at a greater angle than 30° from the horizontal.

Brackets acting as cantilevers must be suitably reinforced.

Slabs.—The effective depth must not be less than 3 inches, and $\frac{1}{4}$ inch to be the least diameter or thickness of reinforcing bars. Any tension cross wires, in mesh or similar reinforcement, to be at least $\frac{1}{10}$ inch in diameter or thickness. Tension bars to be at least 1 inch apart, except at joints or crossings. Mesh reinforcement to be of such dimensions as to allow the concrete to freely pass through the same.

Tension bars or strands to be not further apart than 12 inches, or more than twice the effective depth. When reinforced in one direction only, distributing bars must be provided on top and at right angles to the main bars; these distributing bars to be not more than 18 inches apart, and have an aggregate cross-section of at least 0·08 per cent. of effective cross-section of the slab; or the diameter of each distributing bar must be at least $\frac{1}{15}$th of the effective depth of the slab, and spaced not more than four times the effective depth apart. Wiring or binding shall not be regarded as reinforcement.

Resistance Moments.—Tee beams.—The breadth of the flange shall not be more than $\frac{1}{4}$ of the effective span, or the distance between the centres of the ribs of the tee beams, or twelve times the thickness of the slab, whichever is the least.

Ell beams.—The breadth of flange shall not be more than four times the thickness of the slab, except where the moments due to the eccentricity of the compression are provided for, when six times the slab thickness is permitted.

The **breadth of the rib** of a tee or ell beam shall be not less than $\frac{1}{3}$ depth of rib below the slab.

Buckling in rectangular beams to be provided for when length exceeds twenty times the least width, or thirty times the least width over the outermost longitudinal reinforcement.

A beam supported at its end by a transverse beam must have special provision made as to connecting together, and resisting shear and torsion.

Notes must be added to drawings or diagrams of beams or pillars showing the loads which have been provided for.

Complete formulæ are given for rectangular and tee beams, but these are similar to the data given on pp. 451, 452, 453 (Reinforced Concrete Construction), to which reference may be made.

Part IV.

Pillars shall include piers, posts, columns, detached supports, or any other **vertical** compression member; struts any compression member at any angle.

In calculations for strength, the maximum ratio of length to gyration radius, or of length to effective diameter, shall be taken, the length being measured between the lateral supports irrespective of any splays other than allowed for beams, and the effective diameter to be that over the outermost vertical rods.

Vertical and lateral reinforcement must be provided to all pillars, four full length verticals for rectangular laterals (binding) not less than $\frac{3}{16}$ inch in diameter, and six verticals to curvilinear laterals not less than $\frac{1}{8}$ inch diameter.

Pitch of laterals (binding) shall not exceed $\frac{8}{10}$ effective diameter at any part in length, or sixteen times the diameter of the least vertical. For a length of one and a half times effective diameter at each end, laterals to be spaced not more than $\frac{3}{10}$ effective diameter. All laterals to be firmly secured at each end. The **volume of laterals** to be not less than 0·5 per cent. of the volume of the hooped core.

Verticals to be not less than $\frac{1}{2}$ inch or more than 2 inches in diameter, and have a minimum total cross-section of 1·0 per cent. of the volume of the hooped core. **Joints in verticals** to be made at or adjacent to points of lateral support, and lapped at least twenty-four times the diameter of the upper rod.

In **Rectangular Pillars,** where the ratio between the greater and the lesser diameter exceeds $1\frac{1}{2}$, the cross-section shall be subdivided by cross ties, and the distance apart of verticals in the longer side be not greater than that in the shorter side.

(*As the rules and tables given for calculating the strength of pillars are largely empirical, they are included here in full.*)

Notation for pillars, struts and other compression members.

113.—

A = effective *area* of the pillar, *i.e.* the *area* bounded by the lateral reinforcement (binding) measured to the inside of the hooping.

A_b = cross-sectional *area* of one bar of the *binding* or lateral reinforcement.

A_v = *area* of the *vertical* reinforcement.

c = permissible direct *compressive* stress.

d = effective *diameter*.

f = *form* factor, depending upon form or type of binding or laterals (para. 118).

g = *gyration* radius of the area $[A + (m-1)\ A_v]$ about an axis passing through the centroid of the area.

i = *increased* stress permissible in the core of a pillar suitably hooped.

l = actual *length* of the pillar.

m = *modular* ratio $= \frac{E_s}{E_c}$.

P = *permissible* load or *pressure* on pillars with both ends fixed and with a ratio of virtual length to gyration radius not exceeding 45 (para. 122).

p = *percentage* of volume of binding or lateral reinforcement with respect to the volume of hooped core in any given length of pillar $= 100\ V_v$.

p_b = *pitch* of the *binding* or lateral reinforcement.

s = *spacing* factor depending upon the spacing or pitch of the binding or laterals (para. 118).

V_v = *volume* ratio or *ratio* of the *volume* of binding or lateral reinforcement to the volume of the hooped core in any given length of pillar (paras. 116, 117).

v = *virtual* length of the pillar, strut or other compression member for different conditions of the ends (paras. 122, 124).

114.—A pillar, or other strut, shall be deemed to have fixed ends when the ends are sufficiently secured to other parts of the construction having such rigidity as will maintain the axis at the ends in its original position and direction under all loads less than the crippling load.

115.—In a pillar with fixed ends the stress in the concrete in the area bounded by the lateral reinforcement shall not exceed

c, in a pillar with the minimum of hooping or binding,

i, in a pillar with more than the minimum of hooping or binding, where

$$i = c\ [1 + f\ s\ V_v]$$

116.—The required ratio of the volume of binding or lateral reinforcement to the volume of the hooped core may be obtained from the equation—

$$V_v = \frac{i-c}{c\,f\,s}.$$

117.—The value of V_v actually provided, in either round or square pillars, may be ascertained by direct measurement or from the equation—

$$V_v = \frac{4\,A}{d\,p_b}.$$

118.—

Table showing the value of fs.

Form of Lateral Reinforcement or Binding.	Form Factor *f*.	Spacing of Laterals throughout the length of the Pillar (in terms of diam. of hooped core).	Spacing Factor *s*.	Value of *fs*.
Helical (curvilinear on plan)	1·0	0·2*d*. or less	32	32
Ditto ditto	1·0	0·3*d*.	24	24
Ditto ditto	1·0	0·4*d*.	16	16
Circular hoops	0·75	0·2*d*. or less	32	24
Ditto	0·75	0·3*d*.	24	18
Ditto	0·75	0·4*d*.	16	12
Rectilinear	0·5	0·2*d*. or less	32	16
Ditto	0·5	0·3*d*.	24	12
Ditto	0·5	0·4*d*.	16	8
Ditto	0·5	0·5*d*.	8	4
Ditto	0·5	0·6*d*.	0	0

119.—Notwithstanding any other provision in these regulations the increased stress in the concrete of pillars shall not exceed one-third of the ultimate compressive resistance at four months as given in subsequent table.

120.—The working stress in the vertical reinforcement shall not exceed m times the stress in the concrete.

121.—The permissible load or pressure on pillars with both ends fixed and with ratios not exceeding those in the first column of figures in table below shall be obtained from either of the equations—

For pillars with the minimum of hooping or binding

$$P = c\,[A + (m-1)\,A_v]$$

For pillars with more than the minimum of hooping or binding—

$$P = i\,[A + (m-1)\,A_v]$$

122.—For pillars the permissible load or pressure shall be obtained from the following table :

For the maximum ratio of *virtual* length to *gyration* radius	$\frac{v}{g}$ =	45	54	63	72	81	90
For the maximum ratio of *virtual* length to effective *diameter* for square pillars	$\frac{v}{d}$ =	15	18	21	24	27	30
For the maximum ratio of *virtual* length to effective *diameter* for round pillars	$\frac{v}{d}$ =	12	15	18	21	24	27
Permissible load		P	0·8 P	0·6 P	0·4 P	0·2 P	Nil

For other ratios higher than those in the first column of figures the stress shall be proportional to the above.

123.—Struts shall be subject to all the rules applying to pillars, and the combined stresses at any part shall not exceed the permissible stresses for pillars of like ratios.

124.—For the different conditions of the ends of pillars and other struts mentioned in the

following table, the permissible load shall be ascertained by using the corresponding value of the virtual length in such table in conjunction with paras. 121 and 122:

Condition of Axis at Ends.	Virtual Length, v.
Both ends fixed in position and direction	$v=l$
One end fixed in position and direction and One end fixed in position but not in direction	$v=1{\cdot}4l$
Both ends fixed in position but not in direction	$v=2l$
One end fixed in position and direction and One end not fixed in position and direction	$v=4l$

125.—In the case of arches or other similar constructions the combined stresses at any part shall not exceed the permissible stresses set out in Table of Working Stresses for Beams.

Part V.

External enclosure walls of reinforced concrete formed between reinforced concrete framework must be designed for any loads they may have to carry, but must not be less than 4 inches thick. Where they support vertical loads or resist lateral pressures they must be of the necessary thickness to keep the stresses within the prescribed limits. For enclosure walls of brickwork, stonework, or plain concrete, the topmost 20 feet of their height must be not less than 8½ inches thick, and 13 inches thick for all lower portions. If the walls are formed of hollow blocks, the following minimum dimensions are required. Aggregate thickness, including any cavity, 8½ inches; sides, 2 inches; ends and any interior partitions, 1 inch; clear unsupported span of any part of side, end, or interior partition, four times the least thickness of such part; and aggregate thickness of material, measured at right angles to face of wall, 6 inches.

Any less thickness of walls prescribed under the London Building Act, 1894, may be adopted; but any external wall or portion of same, not supported or secured by the reinforced concrete framework, must comply with the requirements of the above Act.

All walls and facing materials shall be incombustible, and securely connected to the reinforced concrete framework.

Each panel in any external wall must be designed to safely resist a horizontal pressure equal to a static pressure of at least 30 lbs. per square foot, assumed to act uniformly over the area of one panel from either side.

The aggregate area of openings in external walls shall not exceed in a wall of any storey above the ground storey two-thirds of the whole area of such wall, nor the aggregate width three-fourths of the whole length of such wall.

Party and division walls in reinforced concrete shall be not less than 8 inches thick, but party walls between a reinforced concrete building and a steel framed building, or a building constructed in accordance with rules of the London Building Act, 1894, shall in no part be less than 13 inches thick.

All brickwork, stonework, and plain concrete shall be executed in Portland cement mortar.

The pressure on any brickwork supporting reinforced concrete work shall not exceed the values given under Steel Regulations, page 384.

The height of such brickwork with proper lateral supports must not exceed twelve times its least thickness; if without proper lateral supports, six times its least thickness. This thickness must in no case be less than 13½ inches.

Part VI.

The pressure of foundations on the natural soil, or on plain concrete, shall not exceed the values given under Steel Regulations, page 383.

Part VII.

Protection (measured from outer surface of concrete to outer surface of reinforcement) shall not be less than the following values:—Beyond the anchored ends of hooked or upward bent bars, 2 inches, or twice the normal diameter of the bar; vertical bars in pillars, 1½ inches, or the diameter of the vertical bar; longitudinal bars in beams, 1 inch, or the diameter of the longitudinal bar; tensile, compressive, shear, or any other slab reinforcement, ½ inch, or the diameter of bar to be covered; and any reinforcement in any other member, 1 inch, or the diameter of the bar to be covered.

Part VIII.

Materials.—The **Cement** shall be Portland cement of slow setting quality and to British Standard Specification, and one cubic foot of same shall be assumed as weighing 90 lbs. The **Sand** shall be clean and gritty, of hard silicious grains, and free from clay, animal, vegetable, or bituminous matter. It must be capable of passing through a mesh $\frac{5}{16}$ inch square, measured in the clear, and must be separated from the coarse materials before measuring. The **coarse material** (which includes all the ingredients in the concrete except the sand, cement, and water) shall consist of clean Thames or pit ballast or gravel, hard stone, such as granite, basalt, trap rock, or other hard and equally suitable material, and free from clay or any animal, vegetable or bituminous matter. If necessary this material shall be thoroughly washed.

The following materials shall not be used with the sand or coarse material in the composition of concrete :

(*a*) Coal residues, including clinkers, cinders, ashes, coke breeze, pan breeze, slag, and other similar material.
(*b*) Blast furnace slag, copper slag, forge breeze, dross, and other similar material.
(*c*) Sulphates, including plaster of Paris, and other similar material.
(*d*) Limestones, magnesian limestones, marbles, and other calcium carbonates.

The coarse material must pass through a mesh $\frac{3}{4}$ inch square, measured in the clear, and be retained on a mesh $\frac{3}{16}$ inch square, measured in the clear ; it shall be varied as much as possible between these limits. If the material is of a porous nature, it must be thoroughly wetted before mixing with the other materials.

The **volume** of mortar shall be in excess of that required to fill the voids in the coarse material. The volume of sand shall not be more than twice the volume of cement, nor the coarse material twice that of the sand.

The **concrete** shall be composed of cement, sand and coarse material in one of the following or intermediate proportions, and the ultimate compressive resistance shall not be less than that specified for the proportion adopted :

Proportion by volume.			V	*Ultimate* compressive resistance in pounds per square inch.		Value of one-fourth of u_4
Cement.	Sand.	Coarse material.		1 month after mixing, $=u_1$	or, 4 months after mixing, $=u_4$	
1	2	4	6	1,600	2,400	600
1·2	2	4	5	1,800	2,600	650
1·5	2	4	4	2,000	2,800	700
2	2	4	3	2,200	3,000	750

Test cubes shall be not less than 4 inches each way in dimensions, or **test cylinders** not less than 6 inches each way ; the preparing, setting, maturing, and testing of such pieces should, as far as possible, conform to the actual conditions under which the work would be carried out.

All three materials shall be thoroughly mixed dry in batches, and again mixed after wetting. Salt water shall not be used for the concrete.

The concrete shall be placed in its final position before initial set has taken place. For beams, pillars and walls the thickness of the layers of loose concrete shall not exceed three inches before ramming.

As soon as possible after mixing, the concrete shall be properly rammed into the moulds, so as to secure a compact mass, without voids and of the greatest possible density for the proportions used.

All metal reinforcement shall be of steel to the British Standard Specification for structural steel for bridges and general building construction (see page 264).

All reinforcement metal shall be cleaned of all scale, dust and loose rust, immediately before depositing the concrete.

No welding shall be employed in any tensile reinforcement.

The builder or other person directing the work shall furnish the District Surveyor with reasonable proof as to the quality of materials to be used in such construction, and shall make any tests which shall be reasonably necessary.

If testing during the construction or within two months after the completion of the reinforced concrete construction is found necessary by reason of any sign of weakness or faulty work

Important New Work to be Published shortly.

PORTLAND CEMENT AND LIME PRODUCTION

Practical Treatise on the Building, Installation, and Working of Modern Cement and Lime Plants

BY

WILLIAM ALDEN BROWN,

A.M I. Mech. E., Assoc. A.M. Soc. C.E., F.G.S., CONSULTING ENGINEER,
Author of 'The Portland Cement Industry.'

FULLY ILLUSTRATED.

EXTRACTS FROM REVIEWS OF MR. BROWN'S PREVIOUS BOOK

('The Portland Cement Industry.')

'The whole subject has been fully dealt with, and it undoubtedly will rank one of the best if not the first work of reference, and certainly should have a prominent place on the bookshelf of those interested in whatever way in Portland Cement.'—*Stone Trades Journal.*

'The Trade will be under a debt of gratitude to the author for the care he has taken in compiling his facts.'—*Mining World.*

'Mr. William Alden Brown provides a valuable practical treatise on the building, equipping, and economical running of a Portland Cement Plant.'—*Glasgow Herald.*

'Every Architect should study this book.'—*Building News.*

'An up-to-date treatise on an important British industry. The book is well written.'—*The Scotsman.*

'The present manual is very concise and the information is well arranged.'—*The Times Engineering Supplement.*

'The author writes with an intimate and wide practical experience of Cement Manufacture.'—*Vulcan.*

'The book is eminently practical and deserves serious consideration.'—*Nature.*

'Mr. Brown is well qualified to deal with his subject.'—*Western Mail.*

'Such a book cannot fail to be helpful and serviceable in a high degree to the industry or those about to enter it.'—*Contract Journal.*

'An exceedingly practical treatise on making Portland Cement, by an author who has studied his subject.'—*Iron and Coal Trades Journal.*

'Mr. Brown writes with authority and skill.'—*Cardiff and South Wales Journal of Commerce.*

'In Mr. W. A. Brown's book will be found not only descriptions of the various Machinery required, in an up-to-date Cement Factory, but a detailed and careful analysis of the cost of manufacture.'—*The Architect and Contract Reporter.*

'Mr. Brown joins in the demand for renewed exertion, and finds his opportunity for urging greater enterprise and alertness by discussing the present position and prospects, of the Portland Cement Trade.'—*Engineering.*

'A practical Treatise such as this, dealing with the building, equipping, and economical working of manufacturing plant will be welcome.'—*Practical Engineer.*

'Mr. Brown has written with knowledge of his subject from the points of view of past and present.'—*The Illustrated Carpenter and Builder.*

'Mr. Brown's book can be read with profit by the buyer who desires to assure himself that he is getting the best article. We cordially recommend this work to municipal Engineers.'—*Surveyor.*

London: CROSBY LOCKWOOD & SON,
7 STATIONERS' HALL COURT, LUDGATE HILL, E.C. 4.

F. 447

appearing, the builder or other person directing the work shall make such tests, and, if these show faulty work, it shall be reconstructed and reinstated in accordance with these regulations.

The total deflection of beams or slabs freely supported and carrying the uniformly distributed working load shall not exceed 1/600th of the span, when the span is twenty times the effective depth, and shall be in proportion for other ratios of span to depth, and for other conditions of ends and stress and loading.

The superimposed test load shall be one and a half times the superimposed load.

Loading tests shall not be made earlier than 90 days after laying the concrete.

Part IX.

The formwork or centering shall be of such dimensions and so constructed as to remain rigid during the laying, ramming, and setting of the concrete.

The vertical strutting shall be maintained continuous through the lower storeys to the foundations or to other floors or beams which are sufficiently set to afford the required safe support, and all formwork or centering shall be removed without shock or vibration.

Before the formwork or centering under any beam or floor slab is removed, the pillars below such beam or floor slab shall be partially stripped to allow of complete examination on all sides.

Part X.

All reinforcement shall be placed and maintained in the position shown on the drawings, and the concreting in any member shall be carried out as continuously as possible.

Where work has to be recommenced on a surface which has hardened, such surface shall be well hacked, swept clean, thoroughly wetted, and covered with mortar composed of equal volumes of cement and sand.

Concrete laid during dry weather shall be protected against too rapid drying. During the first week of hardening it shall be kept damp by wet sacking or other methods, or by watering daily (Sundays and holidays included).

Concrete shall not be laid when the temperature is below 4° C. (39° F.), and shall be protected when necessary.

Concrete or mortar which has been frozen shall not be used.

The concrete or mortar in any member which has been exposed to frost during the first week of hardening shall be removed, or such members shall be tested as previously provided.

No cutting for piping or any other purpose shall be done which would reduce the strength of any part of the structure below the standard required by these regulations.

Blocks or strips of hard wood, coke breeze, or other equally fire-resisting material may be embedded in the concrete and used solely for fixing purposes, provided that they do not reduce the strength of any part of the structure below the standard required by these regulations, and the area of such blocks or strips at any given cross-section is not included in the calculated compression area of any beam, slab, pillar, or other constructional member.

Soft wood or other equally combustible material shall not be embedded in the concrete.

Wood or other combustible material may be placed on or over the surface of the concrete, provided that any voids or hollow spaces between the combustible and incombustible materials be filled up with incombustible materials.

SYSTEMS OF REINFORCED CONCRETE CONSTRUCTION.

Although there exists a considerable number of so-called independent systems of reinforced concrete construction, the principles underlying the same are in every way similar, and it is only in the manner in which these principles are carried out that any difference arises. The several systems can be readily divided into groups, and the following notes will be sufficient here to indicate wherein one differs from another :—

Systems which make use of Plain Steel Rod Reinforcing Bars.

In the Hennebique system, the main bars are set parallel to the lower or tension face of the beam, some being, where necessary, bent or cranked upwards towards the upper face (as where the beam is continuous over a support). In addition to these bars, flat stirrups are hooked at intervals over the lower bars, and carried upwards towards the upper part of the beam ; these bind the concrete and steels securely together, and assist largely in resisting the shearing stresses. For columns or piles, the rods are grouped symmetrically about the centre of the pile, and are tied together at intervals by means of straps or wire lacing.

The Coignet system is in many respects very similar to the Hennebique, except that generally a number of smaller rods are used, these being in turn bent upwards as they approach the ends of the beam. A continuous top bar is also provided, to which the bent-up members are securely tied or laced. Any additional stirrups or binding ties which are necessary are formed of small

section round bars, varying from $\frac{3}{16}$ in. to $\frac{1}{2}$ in. diameter; these are laced or tied between the lower or main tension bars and the upper bar.

In the Considère system, the portions of any structure under compression are provided with a close-set spiral of steel wire or small-section steel rod, which, by surrounding the concrete and preventing its displacement, enables the enclosed portion to resist safely very high compressive stresses.

A number of other systems in which plain bars are used have recently appeared, the difference between them being in the manner in which the several bars are connected together, and the method of providing for shearing stresses, and for connecting the shear bars to the main bars. Of these might be mentioned the types supplied by the British Reinforced Concrete Engineering Company, the Lewis Construction Company, etc.

Systems in which Bars of Special Sections are utilised.

The Trussed Concrete Steel Company own the 'Kahn' bar and the 'Rib' bar. The former consists of a square or other section bar provided with two projecting wings which can be sheared and bent up to form stirrups or shear members. As these members form part of the main bar there is no possibility of displacement or slipping occurring between the shear and the main bars. From this method of construction it will be obvious, however, that the length and spacing of these shear bars are limited, but in practice it is very seldom that this is in any way objectionable. The rib bar is of round section provided with four ribs or projections running the full length of the bar; cross ribs are set at frequent intervals between the longitudinal ribs, so as to form pockets or recesses into which the concrete can key.

The Indented Bar and Concrete Engineering Company, Ltd., possess a square and a round bar provided throughout their full length with a series of depressions and ridges all round; it is claimed that by arranging the depressions and ridges on opposite sides of the bar the full section of the bar is retained throughout its length. By this formation a mechanical bond or key with the concrete is provided which it is claimed greatly increases the key between the bar and the concrete.

In the Perfector System a round bar with a continuous rib or fin is used, this fin being provided with perforations through which the shear members, etc., are passed.

Other bars providing a mechanical bond are sometimes used, notably some American patents such as the 'Ransome,' which consists of a twisted square rod, etc.

Systems in which the Reinforcement consists of a Metallic Meshwork.

The Expanded Metal Company supply sheets formed from steel sheets of various thicknesses which, by special machinery, have been slit or slotted and expanded to form a metallic network. By embedding this network in the correct position in a concrete beam or floor slab, the necessary metal to resist the tension stresses is provided in a satisfactory and simple manner. For detailed information regarding this material and system, see p. 344.

The Lock Woven Mesh System consists of a mechanically woven fabric made of steel wires crossing at right angles and secured at the intersections.

Reinforced Concrete or Fire-Resisting Floors.

Numerous systems of these are on the market, but they can be grouped together into types, of which the following may be noted:—

(1) A series of hollow or solid blocks of fireclay, concrete, or other material are laid at short distances apart, and the space between same filled up with concrete or cement grouting, with steel rods embedded in same. In this way a series of reinforced concrete beams are formed surrounding the blocks. Where the area to be covered is approximately square, or the proportion of length to breadth does not much exceed 2 to 3, these reinforced concrete beams can be formed on all four sides of the blocks; but where hollow blocks are used, the open ends must be closed up, or provision made to prevent the concrete finding access into the hollows which are intended to lighten the weight of the floor. Of this type may be mentioned the 'Kleine,' the 'Fram,' Diespeker's 'Bigspan,' etc.

(2) Hollow blocks, usually of arched formation, and of a width or span of from 2 to 3 feet, or over, are laid between and supported by lines of rolled steel beams, or of reinforced concrete beams, these latter being made either at works, and delivered and erected complete, or formed *in situ* during the construction of the floor. A level floor surface is obtained by a light filling of breeze concrete over the blocks. Where steel beams or finished reinforced concrete beams are used, the floor can be erected without the use of centering. The dispensing with large masses of wet concrete minimises all trouble due to dripping from the new floor, and allows it to be used immediately after it has been erected. Floors of this nature are manufactured by Messrs. D. G. Somerville & Co., the Armoured Tubular Floor Company, etc.

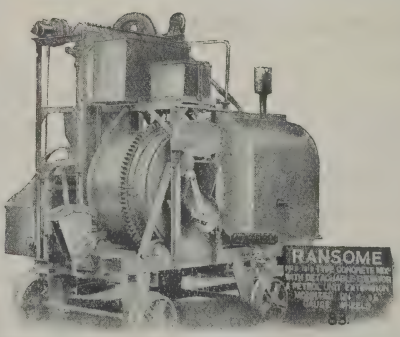
Ransome

ALL BRITISH

CONCRETE MIXERS

made by the largest manufacturers of Concrete Machinery in Europe (highest quality only) and preferred by those who 'KNOW' all over the world. Ransome Mixers are the most scientifically designed and the most substantially built. As a result Ransome Mixers turn out BETTER CONCRETE, in LESS TIME, at LESS OPERATING COST, and they LAST LONGEST. Models and sizes to meet all needs profitably.

RANSOME 'NEW-PRINCIPLE' AERO MIXER



(for reinforced work) produces **MUCH STRONGER** Concrete than has ever been produced before, and at LESS COST, by proportioning and mixing the ingredients by a revolutionary new method that is **100%** efficient.

Piling Equipment.

Tar-Macadam and Asphalt Plant.

A modification of this floor consists in the use of half-arch shaped blocks, which are set into the webs of steel beams, and brought together at the centre where they are lightly grouted at their meeting edges. A levelling-up covering of breeze concrete completes the floor. This type is represented by the 'Fram' arched floor, the 'Carlisle' tubular arch floor, etc.

(3) Concrete tubes of various sections and of considerable lengths may be formed, and reinforced where necessary with steel rods or wire. By placing these close together, it is only necessary to grout in between the joints in the several tubes to complete the floor ready for any top finish: the advantage of a dry laid floor is thus secured. The 'Siegwart,' etc., provide this type of floor.

(4) Floors may be formed of solid concrete slabbing reinforced with plain or special section bars as required, and supported by rolled-steel beams or reinforced concrete beams. Such types are supplied by any reinforced concrete contractor.

(5) Floors provided with a continuous mesh reinforcement :—The floors provided by the Expanded Metal Company and by the Lock Woven Mesh Company may be taken as examples of this class.

Other types of floors are to be met with, each possessing some particular qualification or arrangement peculiar to itself.

DESIGNING REINFORCED CONCRETE STRUCTURES.

Concrete is very strong under compression, but weak under tension. Good average concrete will safely resist a compressive stress of from 600 to 700 lbs. per square inch of section; its tensile strength does not exceed about one-tenth of this value, and may altogether disappear through the formation of minute cracks.

Concrete and steel possess practically the same coefficient of expansion, and therefore expand and contract together under changes of temperature, without developing internal stresses.

Concrete adheres strongly to a clean surface of steel; the average safe adhesion can generally be taken as about 100 lbs. per super. inch. It is thus possible to form a practical and economical combination of concrete and steel, the former material being utilised to resist the compressive stresses, with the necessary steel bars embedded at the points where tensile stresses occur. In certain cases, where the concrete alone cannot provide all the necessary compressive resistance, steel rods are added to assist the concrete; but from an economical point of view this should be avoided whenever possible, for the following reason :—

Steel possesses, on an average, about fifteen times the elasticity of concrete: where steel bars are embedded in concrete to assist in resisting compression, it follows that when the concrete around the bars has been stressed up to its limit, the steel has been compressed to fifteen times that of the concrete only, and is still far from its limit. Notwithstanding this want of economy, it is frequently necessary to utilise steel in this way, as, for instance, in the case of columns, arches, etc., and in beams when sufficient depth, or area of concrete in the compression flange, cannot be obtained.

Steel is very perfectly protected from deterioration by a covering of concrete, and many instances could be quoted to show that a covering of less than 1 inch of good concrete is sufficient to preserve steel almost indefinitely.

In many cases reinforced concrete forms an almost ideal method of construction, particularly where great strength and durability are essential. The strength of the concrete increases with age, and there is no cost of upkeep, as in the case of steelwork, which requires regular inspection, painting, etc.

All structures can have their several members resolved into three types or into combinations of these three types—namely, beams or girders, struts or stanchions, and ties. Beams or girders support loads which act at right angles to their length, and tend to cause bending or deflection of the member. In struts or stanchions the loads act in the direction of the length, and tend to compress the members; in long and slim compression members, however, stresses similar to those in beams may also arise, through bending or side-yielding when the load exceeds a particular value. In ties the load acts in the direction of their length, as in struts, but here the tendency is to produce tension or stretching in the member.

Composite members may be represented by struts or ties which are not placed vertically, and consequently tend to bend by their own weight, and to this latter extent act as beams. Arches also are generally subjected to bending stresses in addition to that of compression.

Beams or Girders.

The bending moment and shearing force values are calculated exactly as in the case of ordinary beams, and reference may be made to pages 292 and 293 for information on this point. Owing to the composite nature of a reinforced concrete beam, however, the determination of the

internal stresses, or of the scantlings of any beam necessary to limit the tension and compression stresses to some specific maximum, are distinctly more complex than in the case of beams formed of a homogeneous material.

The following assumptions, which are practically correct within the usual limits of safe stress and ordinary conditions, are generally admitted, and form the basis on which the formulæ are built up :—

(*a*) The coefficient of elasticity in compression of good concrete is constant throughout the working limit of stress, and for an average 1 : 2 : 4 mixture may be taken as $\frac{1}{15}$ that of the steel reinforcement. For any distance from the neutral axis, therefore, the stress per square inch on the steel is fifteen times that on the concrete.

(*b*) The tensional resistance of concrete is ignored.

(*c*) The stress on the concrete varies uniformly from zero at the neutral axis to a maximum at outer edge ; the stress on the area of the steel is constant.

(*d*) The bond, or adhesion, between the concrete and the steel is sufficient to transmit any stress arising between these two materials.

Considering, in the first instance, a beam formed of some homogeneous material, supported at each end, and loaded so that it tends to deflect, the compressive stress at the upper edge of the beam will be exactly equal to the tensile stress at the lower edge, and these values will gradually diminish towards the centre of the depth, where they will altogether disappear ; this plane of no stress is called the neutral axis.

Assuming that the stresses vary uniformly, fig. 1 may be taken to represent the stresses in any section of the beam, the horizontal distance between the vertical line and the inclined line at any point above the neutral axis will be proportionate to the compressive stresses at the given point ; similarly, the horizontal lengths below the neutral axis will be proportionate to the tensile stress.

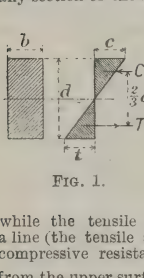

FIG. 1.

The total resistance to compression or extension would be represented by the area of either triangle. The resultant of either of these stresses would act through the centre of gravity of these triangles, or at a distance equal to $\frac{1}{3}$ the perpendicular depth from the base, giving the distance between the two resultants, or the lever arm of the resistance couples, as equal to $\frac{2}{3}d$.

The corresponding diagram for a simple reinforced concrete beam would be that of fig. 2. Here the compressive resistance, which occurs above the neutral axis, is represented, as before, by a triangle ; while the tensile resistance, being that of the steel reinforcement only, is represented by a line (the tensile strength of the concrete is ignored). The position of the resultant of the compressive resistance would pass through the centre of gravity of the triangle, or at $\frac{1}{3}n$ from the upper surface ; the lever arm in this case would equal $d - \frac{n}{3}$.

Where double reinforcement is adopted—that is to say, where a certain amount of steel is introduced into the upper or compression area of the beam to assist the concrete (fig. 3)—the total compressive resistance would, in addition to that of the concrete, include the compressive resistance of the steel ; the combined resultant of these two resistances would equal the sum of the two, and would act at some point between the two independent resistances, the exact position depending on the relative values of these two resistances.

In the case of T beams, or those in which the upper or compression flange is formed in part of the flooring slabs with which the beam proper is combined, two cases arise : the one in which the distance from the neutral axis to top of beam (n) is *not greater* than the thickness of the floor slab (d_s), and the other in which this value (n) is *greater* than the thickness of the slab (d_s). Since the compressive stress is assumed as being resisted by the concrete alone, the first case naturally falls under the same condition as that of a simple beam (fig. 2), except that the breadth of the beam must now be taken, not as the breadth of the reinforced beam only (b_r), but must include a certain portion of the slab at each side of the main beam, or b_s.

The difference between the first and second cases referred to will be obvious by a comparison between figs. 4 and 5. In the former the compression resistance is represented by a triangle, with a resultant acting $\frac{1}{3}n$ from the upper surface ; while in the latter case the compressive resistance is represented by the area of a trapezoid, the point of action being through the centre of gravity of this figure. It should be noted that in this latter case the compressive value of the concrete in the main beam between the bottom of slab and the neutral axis is ignored, as its value is very slight, and the formulæ are much simplified by doing this.

Two extensions of the above two cases are shown in figs. 6 and 7, where double reinforcement is adopted ; the treatment in these two cases is modified generally, as previously noted when referring to figs. 2 and 3 for rectangular beams.

The following series of formulæ for the several types of single and double reinforced beams just referred to will enable the scantlings for any such members to be readily calculated or the designs for these checked with the minimum of trouble.

Rectangular Beams with Single Reinforcement.

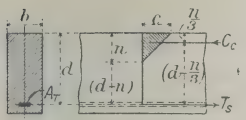

FIG. 2.

$$n=\frac{1}{1+\frac{t}{cm}} \quad . \quad . \quad . \quad . \quad . \quad (1)$$

$$r=\frac{1}{\frac{2t}{c}\left(1+\frac{t}{cm}\right)} \quad . \quad . \quad . \quad . \quad (2)$$

$$t=c\frac{(1-n)m}{n} \quad . \quad . \quad . \quad . \quad (3)$$

$$c=t\frac{n}{(1-n)m} \quad . \quad . \quad . \quad (4)$$

$$A_T=\frac{B}{td\left(1-\frac{n}{3}\right)} \quad . \quad . \quad . \quad (5)$$

$$n=\sqrt{(mr)^2+2mr}-mr \quad . \quad (6)$$

$$R=bd^2\left[tr\left(1-\frac{n}{3}\right)\right] \quad . \quad . \quad (7)$$

$$R=bd^2\left[\tfrac{1}{2}cn\left(1-\frac{n}{3}\right)\right] \quad . \quad . \quad (8)$$

SYMBOLS.

n = Ratio of distance of neutral axis from compression edge of beam to effective depth.
r = Ratio of area of steel to area of concrete = A_T/bd.
t = Tensile stress intensity on steel.
c = Compressive stress intensity on concrete.
m = Modulus ratio = E_s/E_c.
A_T = Area of tensile reinforcement.
B = Bending moment of external forces.
R = Resistance moment of internal stresses.
b = Breadth of beam.
d = Effective depth of beam.

DESIGNING.—Decide values for m, t, c, and trial dimensions for b and d. Calculate n by (1) and r by (2); then value of A_T by (5). R is got from (7) or (8). If any other value of r is used than is given by (2), calculate n by (6) and R by (7) and (8), the lesser of these two values being adopted.

CHECKING A DESIGN.—Calculate r ($=A_T/bd$), and with this determine n from (6); test t and c by (3) and (4). If t exceeds the safe stress, get R from (7); if c exceeds the safe stress, get R from (8), in each case using the maximum safe stress for t or c.

Note.—Where more than one bar is used to form the reinforcement, measure d to the centre of gravity of the group.

Usual Dimensions.—d = one-twelfth to one-sixteenth of span; b = one-half to two-thirds d.

Rectangular Beams with Double Reinforcement.

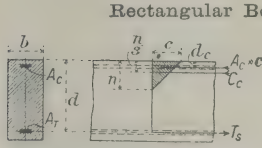

FIG. 3.

$$c_s=\frac{(n-d_c)m\times c}{n} \quad . \quad . \quad . \quad (9)$$

$$c_s=\frac{(n-d_c)_t}{(1-n)} \quad . \quad . \quad . \quad (10)$$

$$A_c=\frac{B-\left[\frac{1}{2}cnbd^2\left(1-\frac{n}{3}\right)\right]}{c_sd(1-d_c)} \quad . \quad . \quad (11)$$

$$A_T=\frac{B-\left[A_cc_sd\left(\frac{n}{3}-d_c\right)\right]}{dt\left(1-\frac{n}{3}\right)} \quad . \quad . \quad (12)$$

$$n=\sqrt{m^2(r_t+r_c)^2+2m(r_t+r_cd_c)}-m(r_t+r_c) \quad (13)$$

$$R=bd^2\left[tr_t\left(1-\frac{n}{3}\right)+c_sr_c\left(\frac{n}{3}-d_c\right)\right] \quad (14)$$

$$R=bd^2\left[\tfrac{1}{2}cn\left(1-\frac{n}{3}\right)+c_sr_c(1-d_c)\right] \quad (15)$$

ADDITIONAL SYMBOLS.

c_s = Compressive stress intensity on steel.
d_c = Ratio of depth to centre of compression reinforcement to effective depth.
A_c = Area of compression reinforcement.
r_t = Ratio of area of steel in tension to area bd.
r_c = Ratio of area of steel in compression to area bd.

DESIGNING.—Calculate n by (1), then c_s by (9) or (10); the area of Compression Steel is got from (11), and the area of Tension Steel from (12). The Resistance Moment is got from (14) or (15).

CHECKING A DESIGN.—Calculate r_t and r_c from scantlings given, and n from (13). c_s is got from (9) and (10), the smaller value being adopted. R is obtained from (14) and (15), the former assuming the concrete, and the latter the steel as stressed to their respective safe limits; the least value of R from (14) and (15) must consequently be taken as the maximum safe R.

See Diagrams on pages 456-457

T Beams with Single Reinforcement.

Class I.—n not greater than d_s

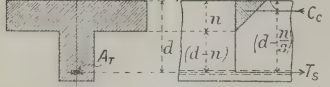

FIG. 4.

$$n=\frac{1}{1+\frac{t}{cm}} \quad . \quad . \quad . \quad . \quad . \quad (16)$$

$$r=\frac{2t}{c}\left(1+\frac{t}{cm}\right)\frac{b_s}{b_r} \quad . \quad . \quad . \quad . \quad (17)$$

$$t=c\frac{(1-n)m}{n} \quad . \quad . \quad . \quad . \quad (18)$$

$$c=t\frac{n}{(1-n)m} \quad . \quad . \quad . \quad . \quad (19)$$

$$A_T=\frac{B}{td\left(1-\frac{n}{3}\right)} \quad . \quad . \quad . \quad . \quad (20)$$

$$n=\sqrt{\left(mr\frac{b_r}{b_s}\right)^2+2mr\frac{b_r}{b_s}}-mr\frac{b_r}{b_s} \quad . \quad (21)$$

$$R=b_rd^2\left[tr\left(1-\frac{n}{3}\right)\right] \quad . \quad . \quad . \quad (22)$$

$$R=b_sd^2\left[\tfrac{1}{2}cn\left(1-\frac{n}{3}\right)\right] \quad . \quad . \quad . \quad (23)$$

SYMBOLS.

n = Ratio of distance of neutral axis from compression edge of beam to effective depth.
r = Ratio of area of steel to area (b_rd).
t = Tensile stress intensity on steel.
c = Compressive stress intensity on concrete.
m = Modulus ratio = E_s/E_c.
A_T = Area of tensile reinforcement.
R = Bending moment of external forces.
R = Resistance moment of internal stresses.
b_s = Breadth of T slab.
b_r = Breadth of rib.
d = Effective depth of beam.

DESIGNING.—Decide values for m, t, c, and trial dimensions for b_r, b_s, and d. Calculate n by (16) and r by (17), then value of A_T by (20). R is got from (22) or (23). If any other value of r is used than is given by (17), calculate n by (21) and R by (22) and (23), the lesser of these two values being adopted.

CHECKING A DESIGN.—Calculate r ($=A_T/b_rd$), and with this determine n from (21). Test t and c by (18) and (19). If t exceeds the safe stress, get R from (22), if c exceeds the safe stress get R from (23), in each case using the maximum safe stress for c or t.

T Beams with Single Reinforcement..

Class II.—n greater than d_s.

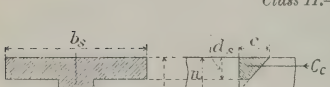

FIG. 5.

$$r=\frac{nd_s\left(1-\frac{d_s}{2n}\right)b_s}{(1-n)mb_r} \quad . \quad . \quad . \quad . \quad (24)$$

$$A_T=\frac{B}{td\left(1-\frac{3nd_s-2d_s^2}{6n-3d_s}\right)} \quad . \quad . \quad . \quad (25)$$

$$n=\frac{d_s^2\frac{b_s}{b_r}+2mr}{2d_s\frac{b_s}{b_r}+2mr} \quad . \quad . \quad . \quad . \quad (26)$$

$$R=b_rd^2\left[\left(1-\frac{d_s}{2n}\right)cd_s\left(1-\frac{3nd_s-2d_s^2}{6n-3d_s}\right)\right] \quad (27)$$

$$R=b_rd^2\left[tr\left(1-\frac{3nd_s-2d_s^2}{6n-3d_s}\right)\right] \quad . \quad . \quad (28)$$

ADDITIONAL SYMBOL.

d_s = Ratio of depth or thickness of slab to effective depth of beam.

DESIGNING.—Decide values for m, t, c, and trial dimensions for b_r, b_s, and d. Calculate n by (16) and r by (24), then value of A_T by (25). R is got from (27) or (28). If any other value of r is used than is given by (24), calculate n by (26), and R by (27) and (28), the lesser of these two values being adopted.

CHECKING A DESIGN.—Calculate r ($=A_T/b_rd$), and with this determine n from (26). Test t and c by (18) and (19). If t exceeds the safe stress get R from (28), if c exceeds the safe stress get R from (27), in each case using the maximum safe stress for c or t.

T Beams with Double Reinforcement.

Class I.—n not greater than d_s.

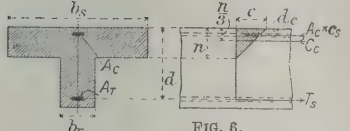

FIG. 6.

$$n=\frac{1}{1+\frac{t}{cm}} \quad . \quad . \quad . \quad . \quad . \quad (29)$$

$$t=c\frac{(1-n)m}{n} \quad . \quad . \quad . \quad . \quad . \quad (30)$$

$$c=t\frac{n}{(1-n)m} \quad . \quad . \quad . \quad . \quad . \quad (31)$$

$$c_s=\frac{(n-d_c)}{n}m\times c \quad . \quad . \quad . \quad . \quad (32)$$

$$c_s=\frac{(n-d_c)}{(1-n)}t \quad . \quad . \quad . \quad . \quad (33)$$

$$A_c=\frac{B-\left[\frac{1}{2}cnb_sd^2\left(1-\frac{n}{3}\right)\right]}{c_sd(1-d_c)} \quad . \quad . \quad (34)$$

$$n=\sqrt{\left[\frac{m(r_t+r_c)b_r}{b_s}\right]^2+\left[\frac{2m(r_t+r_cd_c)b_r}{b_s}\right]}-\left[\frac{m(r_t+r_c)b_r}{b_s}\right] \quad (36)$$

$$R=b_rd^2\left[tr_t\left(1-\frac{n}{3}\right)+c_sr_c\left(\frac{n}{3}-d_c\right)\right] \quad . \quad (37)$$

$$R=d^2\left[\frac{1}{2}cnb_s\left(1-\frac{n}{3}\right)+c_sr_cb_r(1-d_c)\right] \quad (38)$$

SYMBOLS.

n = Ratio of distance of neutral axis from compression edge of beam to effective depth.
t = Tensile stress intensity on steel.
c = Compressive stress intensity on concrete.
c_s = Compressive stress intensity on steel.
m = Modulus ratio = E_s/E_c.
A_T = Area of tensile reinforcement.
A_c = Area of compression reinforcement.
b_s = Breadth of T slab.
b_r = Breadth of rib.
d = Effective depth of beam.
d_c = Ratio of depth to centre of compression reinforcement to effective depth of beam.
r_t = Ratio of area of steel in tension to area b_rd.
r_c = Ratio of area of steel in compression to area b_rd.
B = Bending moment of external forces.
R = Resistance moment of internal stresses.

DESIGNING.—Calculate n by (29), then c_s by (32) or (33), the area of Compression Steel is got from (34), and the area of Tension Steel from (35). The Resistance Moment is got from (37) or (38).

CHECKING A DESIGN.—Calculate r_t and r_c from scantlings given, and n from (36). c_s is got from (32) and (33), the smaller value being adopted. R is obtained from (37) and (38), the former assuming the Steel and the latter the Concrete as stressed to their respective safe limits. The least value of R from (37) and (38) must consequently be taken as the maximum safe R.

T Beams with Double Reinforcement.

Class II.—n greater than d_s.

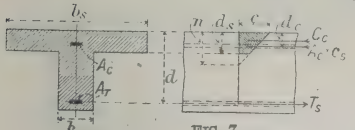

FIG. 7.

$$A_c=\frac{B-\left[\left(\frac{d_s}{2n}\right)cd_sb_sd^2\left(1-\frac{3nd_s-2d_s^2}{6n-3d_s}\right)\right]}{c_sd(1-d_c)} \quad (39)$$

$$A=\frac{B-\left[A_cc_sd\left(\frac{3nd_s-2d_s^2}{6n-3d_s}-d_c\right)\right]}{td\left(1-\frac{3nd_s-2d_s^2}{6n-3d_s}\right)} \quad . \quad (40)$$

$$n=\frac{d_s^2b_s+2m(r_t+r_cd_c)b_r}{2d_sb_s+2m(r_t+r_c)b} \quad . \quad (41)$$

$$R=d^2\left[\left(1-\frac{d_s}{2n}\right)cd_sb_s\left(1-\frac{3nd_s-2d_s^2}{6n-3d_s}\right)+c_sr_c(1-d_c)b\right] \quad . \quad (42)$$

$$R=b_rd^2\left[tr_t\left(1-\frac{3nd_s-2d_s^2}{6n-3d_s}\right)+c_sr_c\left(\frac{3nd_s-2d_s^2}{6n-3d_s}-d_c\right)\right] \quad (43)$$

ADDITIONAL SYMBOL.

d_s = Ratio of depth or thickness of slab to effective depth of beam.

DESIGNING.—Calculate n from (29), then c_s by (32) or (33), the area of Compression Steel is got from (39) and the area of Tension Steel from (40). The Resistance Moment is got from (42) or (43).

CHECKING A DESIGN.—Calculate r_t and r_c from scantlings given, and n from (41), c_s is got from (32) and (33), the smaller value being adopted. R is obtained from (42) and (43), the former assuming the Concrete and the latter the Steel as stressed to their respective safe limits. The least value of R from (42) and (43) must consequently be taken as the maximum safe R.

Note.—In many cases of double reinforcement the compression reinforcement can be placed at the centre of gravity of the compression area; the formula for R could then be somewhat simplified.

Shearing Stresses and Diagonal Tension in Beams.

These stresses and the methods of resisting them require careful consideration in all cases. At any point in a beam, the horizontal and vertical shearing stresses are of equal value, and these stresses may be looked upon as the connecting link between successive increments of tension in the reinforcement and corresponding increment of compression in the concrete ; also, in the case of double reinforcement, in connecting up the increments of tension and compression in the two forms of reinforcement. The tendency of the longitudinal shearing stress is to destroy the adhesion between the concrete and steel, and it is necessary to calculate this value to ensure that no slipping or failure takes place from this cause.

If S represents the total vertical shear, which is equal to the rate of change of the bending moment from point to point along the beam ; s_b the shearing stress between concrete and steel ; O the periphery of reinforcement, whether one bar or a number of bars ; the shearing stress round the bars per unit surface of reinforcement is approximately equal to :—

$$s_b = \frac{S}{O \times 0{\cdot}86d} \quad . \quad . \quad . \quad . \quad . \quad . \quad (51),$$

and this same stress per unit length may be written—

$$s_b\, O = \frac{S}{0{\cdot}86d} \quad . \quad . \quad . \quad . \quad . \quad . \quad (52).$$

The fraction $0{\cdot}86d$ in the above equations represents the approximate average length of the lever arm, or distance between the centre of tension in the steel and the centre of compression in the concrete ; and these equations may therefore be used to give practical values for rectangular or T beams, either with single or double reinforcement.

If s represents the unit horizontal shearing stress in the concrete, the shearing stress per unit length on any width b of a beam is as follows :—

$$s \times b = \frac{S}{0{\cdot}86d} \quad . \quad . \quad . \quad . \quad . \quad . \quad (53).$$

This last formula not only gives the value of the horizontal shearing stress, but also that of the vertical shearing stress at the same point, since both these stresses are always of equal value.

Failure by *diagonal tension* is the cause of numerous mishaps, which are frequently attributed to shear. The maximum diagonal tension in a reinforced concrete beam is largely governed by the amount of the horizontal tension in the concrete as well as that of the shearing stress at the same point. From practical experiments and data it would appear that, with average concrete, beams with no web reinforcement are liable to fail by diagonal shear when the vertical shearing stress intensity, at point of failure, averages about 120 lbs. per square inch. Accepting a factor of safety of 4, the shearing stress intensity given by formula (53) should not exceed 30 lbs. per square inch. With the same factor of safety, the shearing stress calculated by this formula in beams with web reinforcement may be taken at 120 lbs. per square inch.

Web Reinforcement.

This generally consists either of vertical or diagonal stirrups, alone or in conjunction with inclined bars, these latter generally consisting of a portion of the main reinforcing bars bent upwards as required.

The sectional area of steel to withstand the total shearing force at any vertical section, when the shear bar is inclined at an angle ϕ with the horizontal, should be as follows :—

$$\text{Sectional area required} = \frac{S}{t \times \sin\phi} \quad . \quad . \quad . \quad . \quad (54),$$

t being the tensile strength per square inch of the steel.

The resistance to shear and to diagonal tension in a T beam is practically similar to that for rectangular beams, if the breadth in the former be taken as the breadth of the rib (b_r), this value being compared with the breadth (b) of the rectangular beam.

The breadth of rib in T beams (b_r) will usually be found sufficient to resist any horizontal shear when of a size to give sufficient practical space for embedding the steel reinforcing bars, but to allow for any excessive shear, and for diagonal tension, it is well to keep this breadth of ample size.

Inverted Beams.

Where a beam is continuous over one or more intermediate supports, or where a single span beam is securely fixed or built in at its ends, the effect on the continuous beam over the supports or at the ends of the single span beam is to produce reverse bending, and consequently an inversion of the stresses ; the upper portion now being in tension, while the lower portion is in compression. To meet this change in stress, it is usual to bend up a number of the lower reinforcing bars as they approach the ends, and for partial fixing this may be sufficient, but it will generally be found that additional reverse stress bars (sometimes called 'continuity bars') must be added to provide the full area of reinforcement necessary at the upper portion of the beam.

In the case of inverted T beams, it will usually be found that the neutral axis falls outside the slab, and it may therefore be calculated as for an ordinary rectangular beam, of a breadth (b) equal to the breadth of rib (b_r).

Floor Slabs.

By imagining any slab to be broken up into a series of parallel strips, each say 12 ins. wide, it is only necessary to treat each strip as an independent beam, and determine the thickness and the amount of reinforcement according to the particular conditions of loading, etc. The amount of reinforcement thus found will give that required per 12 ins. of width, and may be arranged in the form of a series of small rods set at the required spacing to give this calculated area.

When slabs are reinforced in one direction only, it is generally assumed that the two beams upon which the ends of the reinforcing bars rest will carry the complete load, but should the slab be of approximately square shape, and the reinforcement arranged in two directions, all four beams upon which the slab rests are assumed as taking a share of the total load. In the case of a square slab supported on all four sides, it will be sufficiently accurate to calculate the total load as distributed equally over all four girders. If the slab is of rectangular form, the short or end girders may be calculated as each supporting a triangular area formed by the beam and by lines drawn at 45° from its corners; the long or side girders each supporting one-half the remainder of the slab. This will be obvious from an examination of figs. 8 and 9, where an indication is given of the manner in which two plain concrete slabs failed when tested to destruction.

FIG. 8.

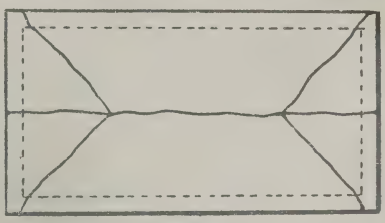

FIG. 9

There is no satisfactory theory as to the stresses in slabs supported on all sides, nor does there seem to be any single generally accepted rule for determining these stresses. The table below gives a series of multipliers for adjusting the bending moment stresses for a slab as calculated in the direction of its length and its breadth; these multipliers are based respectively on the theory developed by Professors Grashof and Rankine, and on the instructions issued by the French Government to the Ingénieurs des Ponts et Chaussées. A comparison of the two series will show a marked divergence of opinion. It is recommended that for ordinary requirements the first rule be adopted, but where the work is carried out under very careful supervision, and first-class material and workmanship are ensured, the second rule may be applied.

Rectangular Slabs supported on four sides.

Value of $\frac{L}{B}$	Grashof and Rankine. $s=\frac{L^4}{L^4+B^4}$	Grashof and Rankine. $l=\frac{B^4}{L^4+B^4}$	French Government. $s=\frac{1}{1+2\frac{B^4}{L^4}}$	French Government. $l=\frac{1}{1+2\frac{L^4}{B^4}}$
1-1	·500	·500	·333	·333
1-1·1	·594	·406	·423	·254
1-1·2	·675	·325	·509	·194
1-1·3	·741	·259	·588	·149

DIAGRAM OF $\frac{B}{bd^2}$ VALUES FOR VARIOUS RATIOS OF TENSION AND COMPRESSION REINFORCEMENT.

be single reinforced, and treated as if supported on two sides only. The use of the foregoing table is as follows :—

In any floor slab of length L and breadth B, calculate the bending moment first for a beam of span B under the total load from the slab, and as supported or fixed at the sides only. Multiply the bending moment thus found by the multiplier s in the table corresponding to the value L/B to determine the actual bending moment on the long axis of the slab. By a similar operation, with a span L, and the use of the multiplier l, determine the actual bending moment on the short axis. By means of the formulæ already given for rectangular beams, the necessary thickness and amount of reinforcement can be determined, and it remains only to distribute this total area of reinforcement in the form of small bars arranged at the necessary spacing throughout the full length and breadth of the slab.

Deflection of Reinforced Concrete Beams.

An ingenious method of calculating the approximate deflection of a reinforced concrete beam or slab was suggested by Mr. Eli White in the 'Engineering Record' for November 9, 1907. The following explanations are based on this method :—

The deflection of a reinforced concrete beam being proportionate to the elongation of the steel tensile reinforcement, this deflection will be similar in amount, for similar tensile stress intensities, to that of a symmetrical beam, whose flanges are each of an area equal to the tensile reinforcement in the reinforced concrete beam, and are placed at a distance apart equal to twice that of

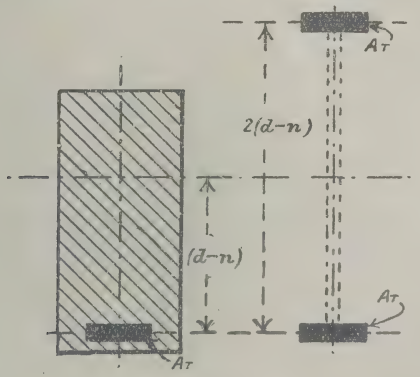

FIG. 10.

the distance between the tensile steel and the neutral axis in the reinforced concrete beam. Fig. 10 indicates to the left a sketch section of a reinforced concrete beam, with tensile reinforcement equal to A_T, and the sketch to the right indicates the section of an imaginary symmetrical steel beam, whose two flanges are each equal in area to A_T and are placed at $2(d-n)$ apart. If t=tensile stress intensity on steel, the

$$\text{Resistance Moment of this symmetrical beam} = 2(d-n) \times A_T \times t. \quad . \quad (55).$$

When any beam is carrying a load, it is obvious that the resistance moment must be equal to the bending moment of the external force acting on the beam.

For this symmetrical beam, the

$$\text{Approximate Moment of Inertia value} = 2A_T \times (d-n)^2 \quad . \quad . \quad . \quad . \quad (56),$$

and taking E at 30,000,000 lbs., the deflection formulæ given in the tables on pages 292 and 293 can be applied to calculate the approximate deflection in any single or double reinforced concrete beam, the correct value for $(d-n)$ being used in the above formulæ.

It should be noted that in the above formulæ the tensile resistance of the concrete has been entirely neglected, and that the formulæ for deflection on pages 292 and 293 are those for beams of uniform section (reinforced concrete beams only more or less approach this condition) ; for these reasons the calculated deflection will generally be distinctly higher than the actual values, which may at times be found as much as 10 to 15 per cent. less than given by these calculations.

The tables on pages 292 and 293 may prove of service in determining *graphically* the bending moment and shearing stress values for various types of loading ; and since these diagrams show clearly the *change of values* they can frequently be used in arranging the main reinforcement and the points where these bars may be bent up to resist shear ; independent shear members can also be set out by the same means.

COLUMNS, PILES, AND WALLS.

SYMBOLS USED IN THE FOLLOWING FORMULÆ.

A = Sectional Area of Concrete in Column.
A_E = Equivalent Area of Concrete to that of Concrete and Steel Longitudinals.
A_L = Sectional Area of Steel Longitudinal Reinforcement.
A_H = „ „ „ Hooping.
W = Safe Load on Short Column.
W_I = „ „ Long „
C_u = Ultimate Compressive Stress on Concrete at 90 days.
c = Safe Stress per square inch on Concrete.
p = Percentage of Longitudinals to Concrete = $A_L \div A$.
l = Length of Column in inches.
I_c = Moment of Inertia of Concrete about Neutral Axis of Column.
I_L = „ „ of Longitudinals „ „ „
G_E = Radius of Gyration of A_E.
b = Smaller Side of Rectangle, or Side of Square.
b_y = Larger „ „
d = Diameter of Round Column, or of Round Rods.
y = Distance of Longitudinal from Neutral Axis, in inches.
x = „ Eccentric Load from Centre of Column.
r_h = Ratio of Volume of Hooping to Volume of Concrete.

Short Columns Reinforced with Longitudinal Bars and Cross Ties.

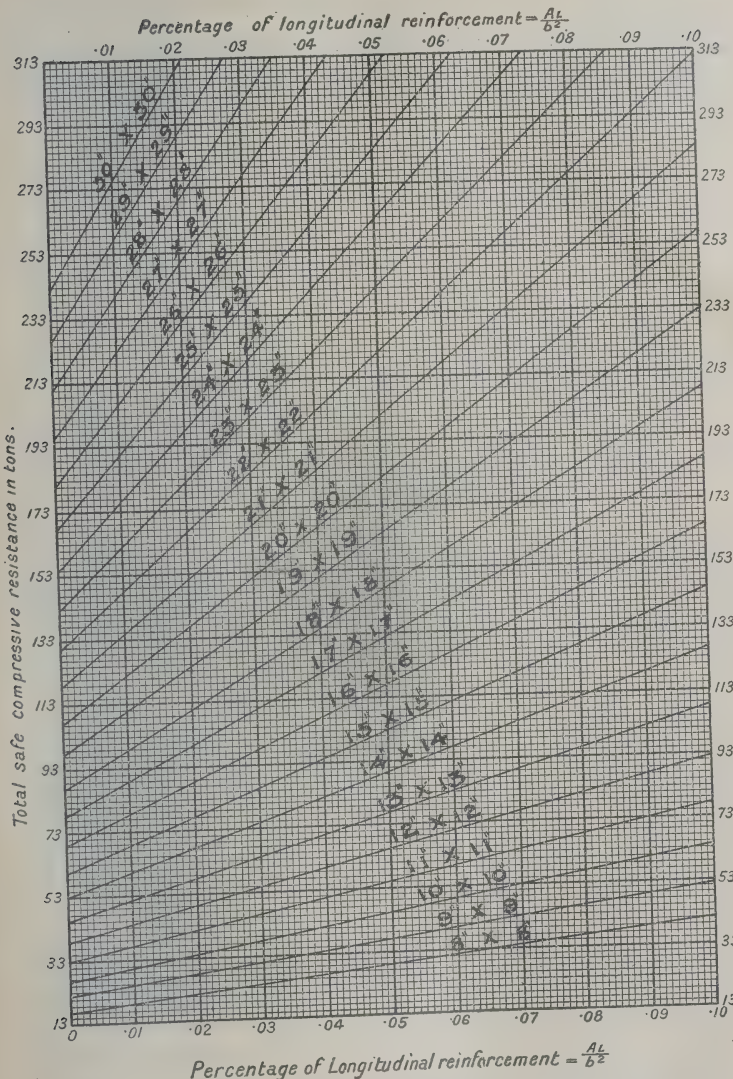
Load Applied at Centre.—

In ordinary cases, the Longitudinal Reinforcement takes the form of round or square steel rods of comparatively small area placed symmetrically about the cross-section of the column; these Longitudinals are held or tied securely together by Horizontal Bindings, which should not be set further apart than twenty to twenty-four times the least diameter of the Longitudinals. This spacing of Bindings should, as a rule, be reduced towards the end of the columns, where in the majority of cases failure first occurs.

When the length does not exceed about 18 times the least diameter or width, and the Maximum Stress per sq. in. on the concrete is limited to 600 lbs., the column may be expected to yield by crushing. Since the Modulus of Elasticity of the Steel Longitudinals is assumed as 15 times that of the concrete, the Maximum Stress on the steel will be 15 times that of the concrete only; 1 sq. in. of steel is, therefore, equal to 15 sq. ins. of concrete. It is sometimes convenient to consider a reinforced column as consisting of concrete only; in which case the sectional area of the concrete would be increased by 14 times the sectional area of the steel reinforcement to give this equivalent area. This may be written :—

$$A_E = A + 14A_L \quad . \quad . \quad . \quad . \quad . \quad (57)$$

Thus, the Safe Load for a short column would be as follows :—



$$W = c\,(A + 14A_L) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (58)$$

It is sometimes convenient to consider the area of the steel longitudinals as a certain percentage of the total area of the concrete, and when this is done, we have the following equation :—

$$\text{Safe Compressive Stress per square inch} = c\,(1 + 14p) \quad . \quad . \quad (59)$$

The following table gives the Safe Stress Values for varying percentages of Steel, and may be used directly when designing Short Columns :—

Percentage of Reinforcement.	Safe Stress, when $c = 600$.	Percentage of Reinforcement.	Safe Stress, when $c = 600$.
½	642 lbs. per sq. in.	4	936 lbs. per sq. in.
¾	663 „ „	5	1,020 „ „
1	684 „ „	6	1,104 „ „
1½	726 „ „	7	1,188 „ „
2	768 „ „	8	1,272 „ „
2½	801 „ „	9	1,356 „ „
3	852 „ „	10	1,440 „ „

TOTAL SAFE LOADS FOR SQUARE COLUMNS, WITH LONGITUDINAL REINFORCEMENT ONLY

High Columns Reinforced with Longitudinal Bars and Cross Ties.

Load applied at Centre.

When the length exceeds about 18 times the least diameter or width there is a risk of Deflection or Lateral Buckling of the column as a whole. It is necessary, therefore, to take into account this tendency, and what is known as Rankine's formula may be used for this purpose. Here the strength calculated as for a short column is reduced in proportion to the ratio of length of the column to its least Radius of Gyration. The formulæ for three forms of end fixings are as under :—

Fixed Ends . . . . . $W_1 = \dfrac{W}{1 + \dfrac{l^2}{34000\,(G_E{}^2)}}$ . . . . (60)

One End fixed, the other free $W_1 = \dfrac{W}{1 + \dfrac{l^2}{25500\,(G_E{}^2)}}$ . . . . (61)

Free Ends . . . . . $W_1 = \dfrac{W}{1 + \dfrac{l^2}{17000\,(G_E{}^2)}}$ . . . . 62)

Where $G_E{}^2 = \dfrac{I_c + 14\,I_L}{A_E}$ . . . . . (63)

The values for I_c may be taken as follows :—

Any Rectangular Section (b = small side) . . . . = $\cdot0833b^3b_y$. (64)

„ Hexagonal Section (b_x = rad. of circumscribed circle) = $\cdot5413b_x{}^4$. (65)

„ Octagonal Section („ „ „) = $\cdot6381b_x{}^4$. (66)

„ Circular Section (d = diameter) . . . . = $\cdot0491d^4$. (67)

If all Longitudinals are of small size and the same section,

$$I_L = \frac{A_L\,\Sigma y^2}{\text{Number of Longitudinals}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (68)$$

Piles, Walls, etc.

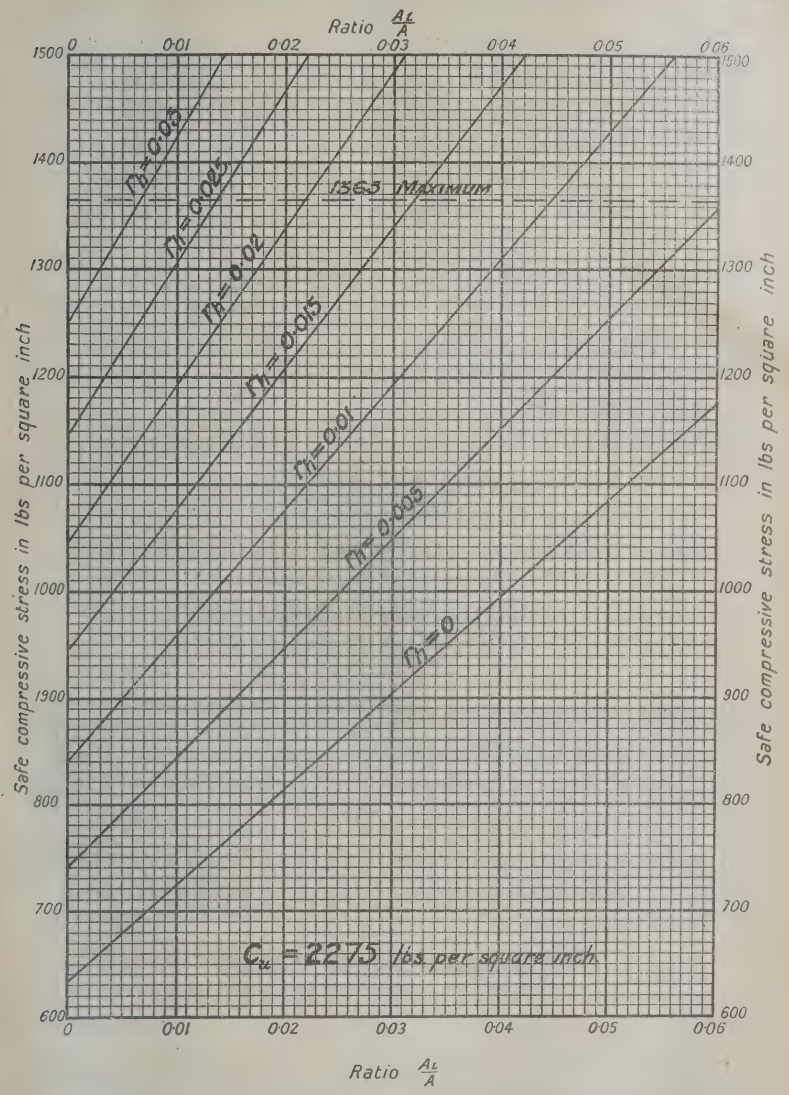
In the case of Piles, the formula given for short columns may be utilised, but it would be well to reduce the Maximum Compressive Stress to 400 lbs. per sq. in., or under, and to close up the spacing of the Cross Ties, particularly towards the ends, owing to the heavy stress which arises during driving. For unsupported lengths of Piles, where they exceed in length 18 times their diameter, the formula for High Columns would be adopted.

In the case of walls, these may be assumed as broken up into a series of independent columns set close together, and their strength calculated as for short or long columns, the particular formula depending on the relation between height and the thickness of wall.

Columns with Eccentric Loads.

When a load is applied at a distance 'x' from the centre of a column, the stress produced may be considered as that due to two independent actions : *first*, a load equal to the Total Eccentric Load applied at the centre of the column, and giving rise to a Uniformly Distributed Compressive Stress, and *second*, a Couple, with a Moment equal to the Eccentric Load × x. This gives rise to a bending tendency, the effect of which may be calculated by considering the column as a Double Reinforced Beam, acted on by a Bending Moment equal in value to this couple. The Maximum Compressive Stress per sq. in. got by this calculation must be added to the Uniform Compressive Stress first got, to arrive at the Maximum Compressive Stress on column at edge nearest the load. At edge furthest from the load the Stress will equal the difference between the Tensile Stress per sq. in. got when calculating as for a beam, and the Uniform Compressive Stress. When the Eccentricity is considerable, the compression at furthest edge may be changed into tension. To resist any such tension, the Steel Longitudinals at that side should alone be calculated on.

Columns with Longitudinal Bars and Steel Hooping.



This type of column was carefully investigated by M. Considère, who showed that by confining the Concrete within a close set Steel Hooping, so as to prevent it bulging, its resistance to Compression was very greatly increased. From experiments made, this Engineer recommended that the hooping should in all cases be circular, that the Longitudinal Rods should be not less than 6 in number, and that the total volume of the Longitudinals should not be less than $\frac{1}{250}$th of the volume of the Concrete. It will be noted that these proportions are given in volumes, not in areas, so as to take into account any necessary pitch of the spiral hooping.

The diameter of the column should be assumed as that within the spiral hooping, and, taking as a unit a length equal to the diameter, we have :—

Unit Volume of Concrete = $\cdot7854d^2$ . . . . . (69)

Unit Volume of Longitudinals = total area of Longitudinals × d . . . . . (70)

Unit Volume of Hooping = Sectional area of coil × $3{\cdot}14d \times \dfrac{d}{\text{pitch}}$. (71)

SAFE STRESS PER SQUARE INCH FOR CIRCULAR HOOPED COLUMNS.

The following is the formulæ adopted by the French Government Commission on Reinforced Concrete :—

Safe compressive resistance $= c(0{\cdot}7854d^2 + 14A_L)$ . . . . . (72)

For pitches of hooping between $\frac{1}{6}d$ and $\frac{1}{5}d$, $c = 0{\cdot}28\ C_u(1 + 32r_h)$. . . . (73)

The value of c should not exceed $0{\cdot}6\ C_u$.

The value of C_u for the usual 1 : 2 : 4 mixture of Concrete may be taken as 2,275 lbs. per sq. in.

The approximate diameters for the hooping may be taken as follows :—

For a pitch of $\frac{1}{5}d$ diameter $= {\cdot}030d$ . . . . . (74)

" " $\frac{1}{6}d$ " $= {\cdot}028d$ . . . . . (75)

" " $\frac{1}{7}d$ " $= {\cdot}026d$ . . . . . (76)

" " $\frac{1}{8}d$ " $= {\cdot}024d$ . . . . . (77)

PIPES, CIRCULAR RESERVOIRS OR BINS, etc.

Symbols used in the following Formulæ.

A_h = Sectional area of hoop reinforcement.
C = Direct compressive stress on the shell.
b_r = Breadth of ring under consideration, in inches.
d = Diameter of pipe or reservoir, in inches.
t = Tensile stress in lbs. on steel reinforcement.
p_1 = Pressure in lbs. per sq. in. on shell.
H_w = Head of water, in feet.

When under Internal Pressure.

(Concrete neglected.)

Consider any circumferential strip or ring, then :—

$$A_h = \frac{p_1 \times d \times b_r}{2t} \quad . \quad . \quad . \quad (78)$$

The total area thus found is divided up into any suitable number of hoops or rings.

Where water pressure has to be resisted :—

$$A_h = \frac{0{\cdot}216H_w \times d \times b_r}{t} \quad . \quad . \quad . \quad (79)$$

In addition to the hoop or spiral reinforcement determined above, longitudinal bars are necessary to strengthen the concrete shell between each hoop to resist the pressure they have to sustain ; the shell here acts as a fixed ended beam or slab of a span equal to the distance between the hoops, and the scantlings calculated by the formulæ previously given for such a type of beam.

Practical considerations generally decide the thickness of the concrete shell, which is usually $1\frac{1}{2}$ to 2 ins. thick for pipes up to 9 or 10 ins. diameter, and seldom exceeds 3 to $3\frac{1}{2}$ ins. even for large diameter pipes. In vertical reservoirs or bins the thickness towards the base must also be such as will safely carry the weight of the shell.

NOTE.—The required reinforcement for circular bins or silos may be determined by calculating 'p' from formulæ (82) or (83) on next page, for two levels say 12 ins. apart ; the difference of the two values thus got will give the pressure per lin. foot and per one foot in height between these levels. Dividing this value by 12×12 (144) will give the average pressure per sq. in., and formula (78) above will at once decide the necessary hoop reinforcement.

When under External Pressure.

(Concrete and hooping both effective.)

$$C = \frac{p_1 d}{2} \quad . \quad . \quad . \quad (80)$$

The safe stress which the shell will sustain depends on the proportion of the steel hooping, and is given in table at foot of page 460. A few trials with varying thicknesses and proportions of reinforcements may be required. The minimum practical thickness of shell is that necessary to give complete protection to the steel rods, and to permit of safe transport and handling.

Longitudinal reinforcement is provided under the same conditions as in the last case.

STORAGE BINS OR SILOS.

SYMBOLS USED IN THE FOLLOWING FORMULÆ.

h = Depth of bin in feet, or height of material above any point.
b = Breadth of rectangular bin, in feet.
l = Length of rectangular bin, in feet.
d = Diameter of circular bin, in feet.
p = Pressure against sides of bin in lbs. per lin. foot of horizontal perimeter.
w = Weight per cubic foot of material in bin.
μ = Coefficient of friction within the material stored.
μ_1 = Coefficient of friction between material and sides of bin.
(For values of the last three items, see table below.)

Bins can be conveniently divided into two classes, as follows :—

First.—Shallow Bins, where the plane of rupture (or the plane along which the material would tend to slide if the sides yielded) passes out through the material itself before it meets the opposite side of the bin, and

Second.—Deep Bins, where the plane of rupture meets the opposite side of the bin within the mass of the contained material.

The particular depth forming the dividing point between the above two classes is obtained by the following formula.

$$h = b \times \left[\mu + \sqrt{\mu \frac{1+\mu^2}{\mu+\mu_1}}\right] \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (81)$$

All depths less than the above value would indicate shallow bins, all greater depths would be classed as deep bins.

For square bins :—

$$\textit{First Class.}—p = \tfrac{1}{2} w h^2 \left[\frac{1}{\sqrt{\mu(\mu+\mu_1)} + \sqrt{1+\mu^2}}\right]^2 \quad . \quad . \quad . \quad . \quad . \quad (82)$$

$$\textit{Second Class.}—p = \tfrac{1}{2} w b^2 \left[\frac{\sqrt{\frac{2h}{b}(\mu+\mu_1) + (1-\mu\mu_1)} - \sqrt{1+\mu^2}}{\mu+\mu_1}\right]^2 \quad . \quad (83)$$

The total pressure on bottom of bin =

(Total weight of material) $-$ ($\mu_1 \times p \times$ perimeter of bin in feet) . . (84)

The maximum pressure on the bottom of a bin occurs when

$$h = \frac{b}{2}\left[\frac{1+\mu^2}{\mu+\mu_1}\left(\frac{4\mu_1}{3\mu_1-\mu}\right)^2 - \frac{1-\mu\mu_1}{\mu+\mu_1}\right] \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (85)$$

For Rectangular Bins the values given by formulæ (82) and (83) will be different for the sides and the ends, since in the latter case the value l would replace that of b.

For Circular Bins substitute d for b in formulæ (81), (83), and (85).

These formulæ are not applicable to the inclined sides of Hopper bins, nor to the conical or spherical bottoms of shallow bins.

DOMES AND CONICAL COVERINGS.

The following graphic method of determining the stresses in domes is only correct for thin coverings of true spherical or conical section, and formed of a material of uniform weight per unit of surface, and capable of resisting both tension and compression. The majority of reinforced concrete domes approximate to these conditions.

For a detailed explanation of the following statements and formulæ, &c., a reference may be made to a Paper by Mr. W. Dunn, A.M.Inst.C.E., F.R.I.B.A., published in the 'Transactions of the Royal Institute of British Architects,' May 21, 1904.

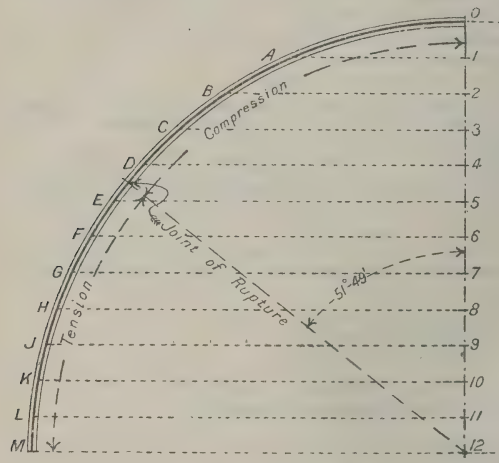

FIG. 11.

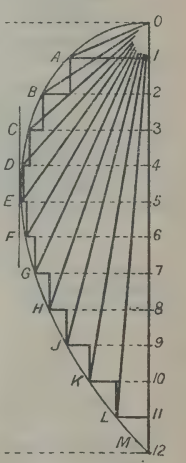

FIG. 12.

To construct figs. 11 and 12. Divide centre line of dome (fig. 11) into any convenient number of parts, and draw the horizontal lines to shell, as 1A, 2B, &c. Draw load line 0–12 (fig. 12) and from O draw radial lines parallel to tangents on the curve at points A, B, &c., till they meet the corresponding horizontal lines; from these meeting points verticals are drawn to the adjacent horizontal lines to complete the zigzag line shown. If correctly set out, the outer meeting points will lie on a regular curve as shown.

Select a scale such that the length 0–12 corresponds with the total weight of the dome; then the several heights between any two horizontal lines can be scaled off direct to give the weight of the portion between these two lines. To same scale, the radial lengths from O (fig. 12) to any point A, B, C, &c., indicate the total pressure on any horizontal section; the horizontal lengths A1, B2, &c., to same scale, give the total horizontal, or radial thrust; the shorter full lines drawn from A, B, &c., give the variation in the radial thrust between the adjoining section lines.

To determine the hoop stress, or that acting at the vertical face of any section, the radial thrust must be divided by $6{\cdot}28 \left(= \frac{\text{Radius}}{\text{Circumference}}\right)$, or by choosing a scale such that the height $0\text{–}12 = \frac{1}{6{\cdot}28} \times$ total weight of dome, the horizontal lengths to this scale will give the radial thrust direct.

The pressure per lineal unit on any horizontal section is equal to the length of the radial line from O to the particular section measured by the modified scale just mentioned, divided by the radius length at this section.

The position of the joint of rupture is at an angle of about $51\frac{1}{2}°$ with the vertical, or where the tangent to the curve in fig. 12 is parallel to the loadline 0–12; this is also the point of no hoop stress.

The addition of a lantern, or other load, at apex of dome will raise the point O in load line, and also the joint of rupture; the formation of a central opening will depress the point O to level of edge of opening, and lower the joint of rupture.

This graphic method will similarly apply to conical coverings.

ARCHES.

The designing of concrete arched bridges as a rule should be undertaken only by experts, as the accurate determination of the stresses, and the economical arrangement of concrete and steel to resist those stresses, calls for a large amount of skill and experience. The following diagrams and brief explanations will serve to indicate the manner in which such arches can be designed, or the strength of existing arches calculated.

Arched bridges may be divided into three general types :—

1. That in which a continuous arch is provided, without joints or hinges, and connected rigidly to the abutments.

2. Where the arch is hinged or jointed at each abutment, but is continuous between these two points.

3. Where the arch is hinged or jointed not only at the abutments, but also at the centre.

The existence of a hinge or joint implies that any stress in the arch ring must pass through the centre of the joint, and it is necessary to keep this in view when drawing the equilibrium polygon, and to arrange that this polygon passes through the centre of all joints.

Fig. 13 indicates an arched bridge of the first type, viz., that in which no joints occur, and consequently the position of the stresses in the ring is not restricted, as it would be by the introduction of joints or hinges. The complete width of the bridge may be considered as divided up into a series of strips, each say 12 inches wide, and attention given to one strip only. In the event of any irregularity in the loading of one strip more than the other, as for instance the outer edge of the arch which carries the parapet wall, such a strip would be considered independently. The complete span would be divided into a number of sections as indicated by dotted lines, and the weight or load on each section carefully calculated ; these weights can be taken as acting each through the centre of gravity of the section.

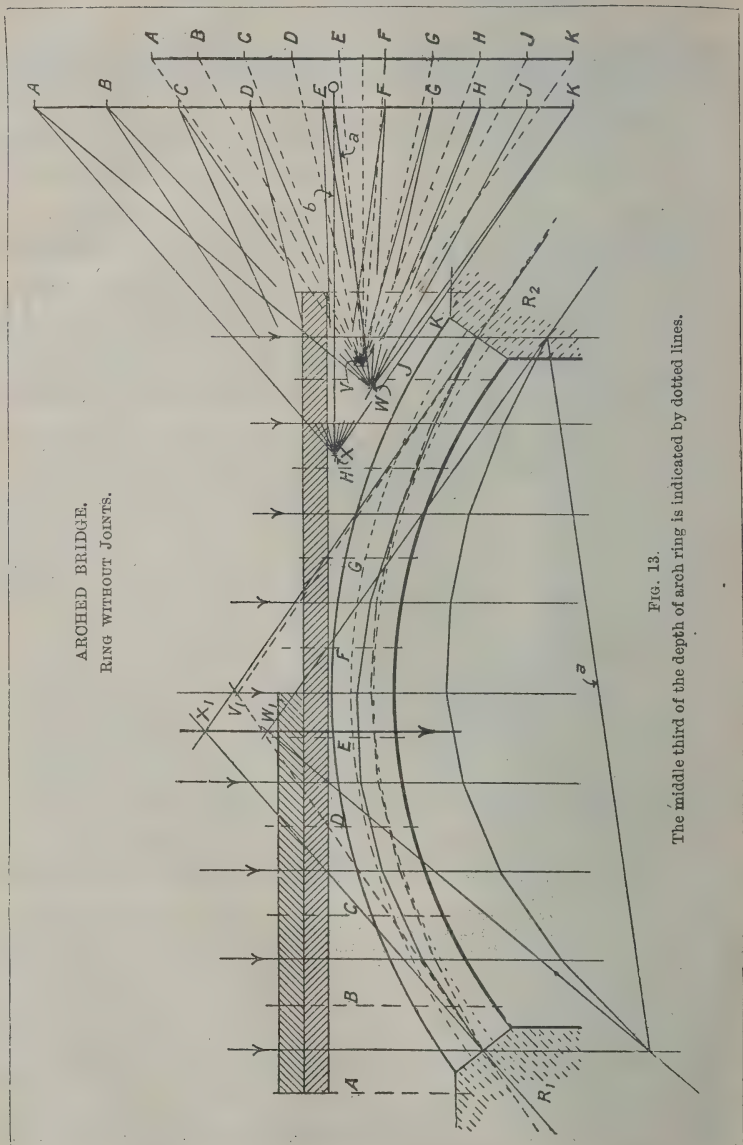
Assuming in the first place that the total dead load is practically uniformly distributed over the length of the bridge, so that the weight or load at each section is equal, the shorter line of loads A, B, . . . K, to the right of the illustration can be set up, and a polar point, or pole, V, chosen. Since the load is uniformly distributed, the vertical reaction at each abutment will be equal to one half the total load, and as the closing line of the equilibrium polygon must be in the same line as that joining the two points in the abutments where it is desired that the resultant pressures should occur, and in this case these two points are on the same horizontal line, a horizontal line would be drawn from the centre of the line of loads and the point V chosen on this line, at such a distance from the load line as to limit the height or rise of the equilibrium polygon drawn on the arch ring, so that it may coincide, as nearly as possible, with the centre line of the arch. The approach of this polar point to the load line tends to raise the centre of the equilibrium polygon, while a movement in the opposite direction will depress the centre.

If the loading is not uniform, as for example where the live load covers half the length of the bridge, the load line would take the form somewhat as that indicated by the longer line A, B . . . K, and to determine in the first place the vertical reaction at each abutment, a focal point W is chosen at random, and an equilibrium polygon drawn, as shown below the arch ; the closing line of this latter, marked *a*, gives the direction in which a line must be drawn from the point W in the polar diagram, so that its intersection with the load line will divide this latter into two portions, the vertical height, A O, giving to scale the vertical reaction at the left abutment, or the A end of arch, while the lower length, O K, gives the corresponding value for the opposite abutment. Having found this point O, a horizontal line is drawn from O on which the new focal point X must lie, to ensure the starting and finishing point of polar diagram occurring at the required points on the abutments. The position of X must be chosen, by one or two trials if necessary, so that the equilibrium polygon line, as before, is as near as possible to the centre line of the arch ring.

If the ring is formed of stone or brick, and no tension can be resisted, it is essential that all equilibrium polygons, for any possible combination of loads, should lie within the middle third of the depth of the arch ring ; if a line of any of the polygons extends beyond this limit, tension stresses are likely to develop.

The length of the outer rays or lines on the polar diagram will give the values of the tota resultant pressures at each abutment, and assuming that the abutments are of sufficient strength and stability to give this required resistance, the values calculated for the stresses in the arch ring by this method are correct. Should, however, the abutments tend to yield, the amount of horizontal reaction is limited in value, and the distance of the point X from the load line must not indicate a horizontal stress greater than the abutments can offer ; the equilibrium polygon drawn under these conditions would in all probability pass above the centre of the arch ring, and thereby indicate that excessive bending stresses arise in the ring, tending to cause failure or collapse through the arch sinking downwards. If by any means the abutments are forced together, or if the ring of the arch tends to increase in length, as by a rise of temperature, the polar point would tend to move further from the load line, and the equilibrium polygon would tend to fall below the centre of the arch ring, indicating the tendency of the ring to be forced upwards, heavy stresses being again produced.

In the case of types Nos. 2 and 3 the positions of the centre of the hinges or joints limit the position at these points of the equilibrium polygon, and in fig. 14 a diagram is shown of a



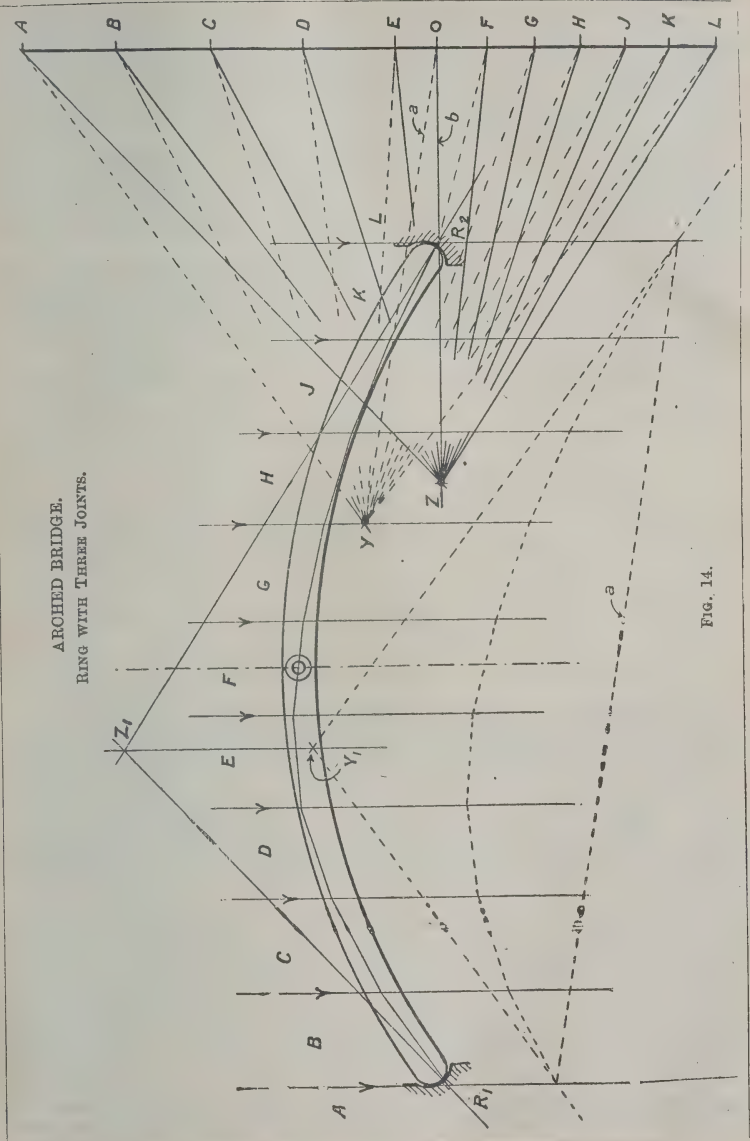


Fig. 13.

The middle third of the depth of arch ring is indicated by dotted lines.

ARCHED BRIDGE.
RING WITH THREE JOINTS.

FIG. 14.

three-hinge arch sustaining an unequally distributed load. After drawing the load line A, B. . . . L, a polar point Y is chosen, and the equilibrium polygon, shown in dotted lines, is completed, the closing line *a* determining the point O in the line of loads which divides this line into two sections, giving the vertical loads on the two abutments. A line from this point O drawn parallel to a line joining the centres of the hinges at the abutments, will give the line *b*, and on this line a point Z is chosen, such that the equilibrium polygon shown in full lines on diagram will pass through the centre hinge. If this centre hinge does not exist, as in type No. 2, the same process would be gone through, but here the aim would be to keep the equilibrium line as near the centre of the depth of the arch ring as possible.

The value of hinges or joints in the arch ring is that definite points are determined at the abutments through which the total thrust must pass, as also does a hinge in the centre of the rib ; another marked advantage of a centre hinge is that a slight yielding of the abutment would imply only a drop in the centre of the ring, but would not induce the excessive bending stress such as would arise in the case of a ring without a centre hinge. Again, a slight lengthening in the arch due to a rise of temperature would not produce excessive stress, owing to the fact that the arch would be enabled to rise more or less freely in the centre.

In addition to drawing equilibrium polygons for the total dead load only, it is advisable in the majority of cases to draw similar polygons for live loads extending over say $\frac{1}{3}$, $\frac{1}{2}$, and $\frac{2}{3}$ of the complete span, and also for the live load confined to the centre of the bridge, and extending for one-fourth of the span on each side of the centre. No other arrangement of the live load is likely to give higher maximum stresses than got from these positions.

The next step necessary is to determine the actual stresses in the arch ring itself, and this may be done as follows :—

Figs. 15 and 16 indicate to a larger scale a portion of the arch shown in fig. 14 about

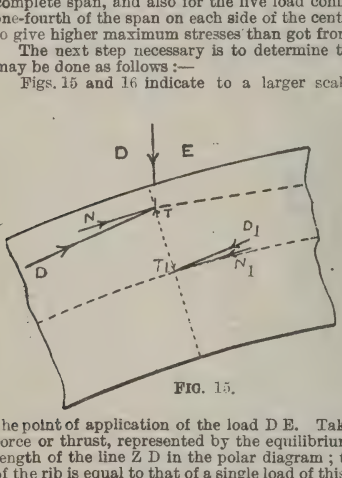

FIG. 15.

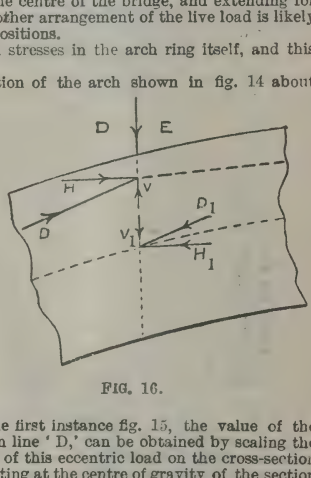

FIG. 16.

the point of application of the load D E. Taking in the first instance fig. 15, the value of the force or thrust, represented by the equilibrium polygon line ' D,' can be obtained by scaling the length of the line Z D in the polar diagram ; the effect of this eccentric load on the cross-section of the rib is equal to that of a single load of this value acting at the centre of gravity of the section (and producing a uniformly distributed compressive stress over the whole section), along with a couple value equal to the load or thrust, multiplied by its normal distance from the neutral axis of rib ; this couple produces a bending tendency, and gives rise to tensile stress at the distant edge and compressive stress at the near edge of the section. The combined result is an increase of compressive stress at the near edge, and a reduction at the far edge. As previously mentioned, should the force act without the middle third of the depth of the ring, the tensile stress due to the couple will be in excess of the uniformly distributed compressive stress, and tension at the distant edge will arise.

Considering the bending moment effect of the couple referred to above. D, D_1, fig. 15, indicate the two forces forming the couple ; these are of value equal to the thrust indicated by the equilibrium polygon, the one acting along the polygon line, and the other at the neutral axis of the arch ring. Each of these forces may be resolved into two forces without altering the effect on the rib ; thus D may be resolved into a force N acting normal to the radius line (shown by a dotted line), and a small force T acting in the direction of the radius line. Similarly D_1 can be resolved into two forces N_1 and T_1, and as T and T_1 are of equal value, but act in opposite directions, these will neutralise or balance one another, with the result that the two forces N, N_1, acting normal to the radius line, will produce the same effect as the two original forces D, D_1. It may be pointed out that the normal force N alone serves to produce direct stress in the arch rib, the smaller resolved force T producing shearing stress : this shearing stress, however, is always very small, and may frequently be neglected.

In calculating the bending moment by means of these resolved forces it is necessary to determine the value of N for each point under consideration ; these calculations, however, can be simplified by modifying this treatment, as indicated in fig. 16. Since the effect of the force D

is not altered by resolving it into any two forces, a vertical line may be chosen, and D resolved into force H acting horizontally, and V acting vertically ; D, would be similarly resolved into H_1 and V_1. A glance at the polar diagram will show that at any point in the equilibrium polygon the horizontal component of the thrust is constant, and can be determined by scaling the length Z O ; from this it will be evident that the values H, H, in fig. 16 will be constant for any section of the arch, and since V, V, neutralise one another, the constant forces H, H, remain. For any section of the ring, therefore, it is only necessary to carefully measure or calculate the vertical distance between polygon line and centre of gravity of the arch ring, and to multiply this by the constant horizontal thrust H, to determine the bending moment value at the point under consideration ; the addition of the uniformly distributed load value will give the complete stress throughout this section.

Thus, if the thrust H, fig. 16, is 40,000 lbs., the vertical distance between H and the neutral axis 8 ins., and the dimensions of the arch ring under consideration are 20 ins. deep × 12 ins. wide ; the uniformly distributed compressive stress throughout the section will be $\frac{40,000}{20 \times 12} = 167$ lbs. per sq. in. ; the B M $= 40,000 \times 8 = 320,000$ inch lbs., and the maximum compression and tension stresses at upper and lower edges of the section $= \frac{320,000 \times 10 \times 12}{12 \times 20^3} = 400$ lbs. This gives the total maximum compression at the upper edge $= 167 + 400 = 567$ lbs. per sq. in., and the total tension at lower edge $= 400 - 167 = 233$ lbs. per sq. in., necessitating the addition of steel reinforcement at the tension portion.

Temperature stresses due to variations in the temperature of the arch may be considerable, and should be carefully examined ; a rise of temperature (by causing expansion) tends to increase the compression stress, while a fall has the opposite effect. The result is very similar to that of increasing or reducing the horizontal thrust (or the distance Z O in the polar diagram) throughout the arch. Owing to the mass of the materials, and its non-conducting nature, the range of temperature in concrete arches will probably not exceed 15° to 20° Fahr. between summer and winter seasons.

Specification for Reinforced Concrete Work.

The following sketch specification may be of assistance. It can be modified to any required extent to meet special conditions.

(Date) ——————

Specification for Reinforced Concrete Work to be executed in erecting New Premises at ——————— for Messrs. ———————

Engineer.

Architect.

General Description and Conditions.—The Structure will be erected in strict accordance with the Engineer's Drawings Nos. ..... and ..... and to any further Detail Drawings to be afterwards provided.

The Structure will consist of (*give general description*). The Foundations shall be taken out to (*the clay, ballast?*). The Maximum Load at this point must not exceed ..... tons per square foot. The average depth of foundations may be assumed as ..... below datum level.

The whole of the work included in this Contract shall be constructed of the best materials and workmanship, and shall be carried out to the entire approval of the Consulting Engineer, and be completed to his satisfaction.

No variations or alterations from Specification or Drawings shall be permitted unless same are approved in writing by the Consulting Engineer.

Immediately on acceptance of his tender, the Contractor must provide a complete and detailed Bill of Quantities (priced in ink) for this work. Should any variations or alterations occur during the carrying out of the work, the variations shall be measured up and priced according to the Bill of Quantities, and any necessary additions or deductions thereafter made from the quoted lump sum price. Any materials or labour required during the progress of the work which are not indicated in the Bill of Quantities shall be paid for at Rates or Prices to be agreed with the Engineer.

The Contractor will be responsible for meeting all requirements of the London County Council, or other Local Authorities, with regard to the mode of construction or the carrying out of same, and shall at once notify the Consulting Engineer should such requirements necessitate any modification in his designs or details.

The Contractor will be held responsible for setting out the Works, and for amending any errors due to inaccuracy, or other cause, at his own cost.

The Contractor must provide for these Works all labour, tools, tackle, boards, horsing, centering, scaffolding, cartage, water, etc.

The Contractor must provide and maintain proper sheds, latrines, and other accommodation for the use of workmen, and proper sheds and shelters for the protection of materials.

The Contractor will be held responsible for all losses, accidents, and damages that may happen to the works, adjoining properties, or persons during the progress, and caused by the execution of the Works.

The Contractor will be bound to complete all the Works contained in this Specification, etc., within ..... months of the date of signing the Contract or obtaining possession of site, under the penalty of ..... per week or part of a week as liquidated and agreed damages, except the delay in the opinion of the Engineer arises from causes beyond the control of the Contractors, in which case the Engineer shall grant an extension of time in writing.

The Contractor must allow for making good at his own expense any defect or defects which may become noticeable in the Works during a period of twelve months after certified completion.

Samples.—Samples of all materials must be submitted to the Consulting Engineer, and approved by him in writing before same are used. All materials rejected must be removed immediately from the vicinity of the Works.

Cement.—The Cement used must be the best quality of British Portland Cement, of an approved make, and guaranteed to conform to the Specification of the British Standards Committee for slow-setting cement. Before being used all Cement must be tested, as required by the Engineer, at the Contractor's expense. The Cement should be delivered to the Site in sealed bags bearing the maker's name and the weight of the cement contained.

Cement shall be stored on the Site in such a manner as to permit of easy access for proper inspection and identification. The building used for same must be raised from the ground, and properly weatherproofed to protect the cement.

Sand.—The Sand used shall be clean, sharp, and coarse, composed of grains of various sizes up to particles which shall pass a ½-inch square mesh, but of which at least 75 per cent. shall pass a ⅛-inch square mesh. It shall be free from all ligneous, organic, or earthy matter.

Aggregate.—This must be composed of Thames ballast; screened, broken stone of a hard close-grained quality; or gravel, cleaned free from organic matter, and angular, varied in size as much as possible, and to pass through a ¾-inch ring, but not through a ¼-inch ring.

Proportions of Concrete.—(*Here specify the composition of concrete, which for usual requirements, may be 1 part cement, 2 sand, 4 aggregate. Foundations are frequently made of a weaker mixture, say* 1 : 3 : 6.) These proportions are approximately correct, but in all cases sufficient sand must be added to fill the interstices. The proportioning should be done in an approved manner, as by means of a bottomless box, to insure each of the materials being accurately measured.

Mixing of Concrete.—The concrete must be thoroughly well mixed in a suitable machine, sufficient clean water being added to convert the whole into a semi-liquid mass, which will quiver under the blows of the rammer. The water for each batch of concrete must be measured in a small tank, so as to insure the same amount being used each time. When consent is given to mix any of the concrete by hand, it shall be done as follows:—The necessary quantity of the three materials—coarse aggregate, sand, and cement—shall be measured separately, 5 per cent. more cement being added in addition to the above specified amount. The materials should first be thoroughly mixed dry, then the necessary amount of water added, and the mixing continued till the concrete shows a uniform colour. As far as possible, the mixture shall always be brought to the same degree of wetness. A competent foreman must be in constant attendance at the mixer, to give his approval of every batch which leaves the machine.

Allowable Working Stresses.—(*Here specify maximum stresses desired, or state requirements to be those embodied in Report of R.I.B.A. Joint Committee.*)

Steel Reinforcement.—All steel used should have a tensile strength of not less than 60,000 lbs. per square inch of section, and an elastic limit of not less than 50 per cent., nor more than 60 per cent. of the ultimate tensile strength, with an elongation of not less than 20 per cent. in a length of 8 ins. Any bar must stand bending cold round a bar of its own diameter, through an angle of 180°, and should close down upon itself without fracture on the outside of the bent portion. All welding will be prohibited, unless where absolutely necessary, and must be done only with the sanction of the Consulting Engineer.

All bars shall be free from scale, flaws, or other imperfections, and from oil, but a slight coating of rust is not objectionable. Wherever cinder concrete is used, the bars before being placed in position should receive a coating of neat cement grouting.

Any temporarily protruding bars which shall be exposed to the weather for any period must be protected from rusting by a thin coat of cement grout.

Centering.—All centering must be of dressed timber with close joints, and must be true to line, and sufficiently braced and strutted to be rigid and free from measurable deflection when carrying the dead load of the concrete which is to be placed upon it. A slight camber of ¼ in. per 10 ft. of span should be given to all beams, &c. It must also be without appreciable deflection when men are working upon it, and barrows, &c., are being wheeled over it. The joints must be tight, so as to prevent leakage of the liquid cement. The centering shall be arranged so that the sides of the columns can first be removed, then that at the side of beams, and below floor slabs, and finally that below the beams themselves. The time of removal of these several portions shall be arranged with the Consulting Engineer.

Placing of Reinforcement.—All bars must be accurately placed in the exact position shown on the detail drawings, and great care must be taken that they are not displaced during the process of packing the concrete around them. Where, for unavoidable reasons, it is necessary to stop the concreting work, care must be taken to place in position all the bars which will be embedded in the portion of the concrete work which is being executed.

Placing of Concrete.—Before any concrete is put in position a careful inspection of the centering must be made, to ascertain that no dirt, shavings, loose stones, etc., have been allowed to remain in or about the centering, and the woodwork should be well watered to avoid any danger of its sucking up too much moisture from the concrete.

All concrete shall be placed in its final position in the work as soon as possible after mixing. In no case must more than half-an-hour be allowed to elapse before this is done. The concrete must be placed gently into position, in layers not exceeding 6 inches thick, and must not be tipped or dropped from a height. It must then be thoroughly rammed into position, great care being taken to see that the steel reinforcement is thoroughly surrounded by the liquid cement, and that no voids or cavities are left. This can be insured only by repeated ramming with a suitable tool.

In hot weather the concrete shall be continually moistened for at least a week after placing in position.

In beams and slabs, if any difficulty is found in getting the concrete to pass through the bars which have been placed in position in the bottom of the timber centering, the concrete at the bottom of the beam should be made of finer and more liquid consistency than that used elsewhere, so that it may freely pass between the bars.

Cessation and Recommencement of Work.—Stoppage of work in laying concrete in slabs, beams, etc., will be allowed only at the centre of the span of the slab, or a beam, and the joint with the new concrete should be a vertical plane at right angles to the direction of the span of beam or slab. No joint must be made towards the ends of beams or slabs, or close to a concentrated load.

Wherever a stop has been made in concreting, before recommencing the work, the surface of the existing concrete must be carefully washed with a stiff brush to remove loose particles and dust, and a thick grout of neat cement must be poured over it before the concrete is rammed against it.

Frosty Weather.—No concreting work should be done when the temperature is near or below freezing point. If a frost comes on shortly after any concreting work has been completed, this should be very carefully covered over with sawdust, straw, or sacking, and the centering must be allowed to remain up for at least as long a time after the complete disappearance of the frost as it would have been left in position if no frost had occurred.

Finish.—All concrete roofs and gutters must be laid with the necessary fall, and finished for asphalte, all as may be directed.

All floors shall be finished. (*Here state whether cement, granolithic, preparation for wood blocking, or other covering is desired.*)

The top surface of all outside walls to be weathered.

Tests.—The Maker's Certificate must be provided, when required, with each lot of steel reinforcing bars supplied, but in addition to this the Consulting Engineer shall choose whatever test pieces he may desire from the material delivered, and shall have same tested by Messrs. Kirkaldy, or other firm, and should the result not comply with Specification the right is reserved to condemn all bars included in same consignment.

The cement shall be tested as required, and must comply with the Specification. Cubes of concrete from the material used shall be made as and when directed, and these shall be tested for crushing strength by Messrs. Kirkaldy, or other firm.

The Consulting Engineer shall select at least one bay in each floor, or the equivalent, and these bays shall be tested to $1\frac{1}{2}$ times the safe superimposed load, by means of bricks, cement bags, or in such other manner as the Engineer may decide. Should the deflection under this test exceed $\frac{1}{800}$th part of the span, or should the beam or floor slab fail to regain its normal position after the removal of the load, or show any indication whatever of weakness, the building shall be considered unsafe, and the contractor shall carry out at his own expense such additional work as the Engineer may consider necessary to make the building secure.

The cost of all such testing shall be borne by the Contractor.

Practical Notes.

Wood Strips.

Particularly long lengths of wood for nailing strips in concrete beams should be avoided; they have been known to absorb the moisture from the concrete, and cause serious cracks in the beams. Short plugs are the safest, and where a nailing strip must be used flush with beams, a moulded impress of the wood strip should be made and the strip then removed, and only fixed when the concrete beam is thoroughly dry, it being then secured by means of the plugs. (*Horobin.*)

Durability.

Reinforced concrete will last as long as plain concrete in any situation provided that certain special precautions are taken during its construction. The precautions to be taken are as follows: The materials (cement, sand, and stone) must be of good quality. They must be most carefully and thoroughly mixed and scientifically proportioned, so as to be practically water-proof and air-proof. The mixture must be fairly wet, and must be well punned into position so as to minimise voids. The aggregate should be as non-porous as possible, and any aggregate which

is known to have a chemical action on steel should be avoided. The aggregate should all pass through a $\frac{3}{4}$ in. mesh. The concrete covering should in no case be less than $\frac{1}{2}$ in., and it is suggested that if round or square bars be used the covering should not be less than the diameter of the bar. In structures exposed to the action of water or damp air the thickness of covering should be increased at least 50 per cent., or the size of the aggregate should be reduced so as to ensure a dense skin. In the case of structures exposed to very severe conditions the concrete might be covered with some impervious coating as an extra precaution. The reinforcement should be so arranged that there shall be sufficient space between one piece and its neighbour to allow the concrete to pass and to completely surround every part of the steel. All steel should be firmly supported during the ramming of the concrete, so as to avoid displacement. It should not be oiled or painted, and thick rust should be scraped and brushed off before placing. The scantling of the various members of the structure should be sufficient to prevent excessive deflection. If electric mains are laid down very great care must be taken that no current is allowed to pass through the reinforced concrete. Fresh water should be used in mixing, and aggregates charged with salt should be washed. These recommendations have regard only to the prevention of corrosion of steel and not to fire-resistance or any other property of reinforced concrete. (*Committee of the Concrete Institute.*)

Causes of Failures in Concrete Structures.

Owing to the failure of several reinforced concrete floors in the United States within ten or a dozen years of their construction, Prof. H. J. M. Creighton, of Swarthmore College, examined a large number of reinforced concrete structures in which cracks were developing, and found that in every case the cracks ran along the reinforcing rods, due to the deteriorating action of salt and brine on the concrete. Solutions of the chlorides reacted with the lime and the silicates in the concrete, and penetrating to the iron of the reinforcement converted it into oxide and hydrate, which occupy more space than the metal and force the concrete apart. It was therefore necessary to waterproof reinforced concrete structures which will be in contact with brine, to cease to use in the concrete beach gravel which has not been thoroughly washed with fresh water, and never to add salt to the concrete to prevent it freezing during building operations in cold weather.

Cracking.

According to a recent report, the cracking of reinforced concrete structures is markedly prevalent in the Philippine Islands. A study of this trouble has shown that not a single structure showing rusted steel has been free from salt, the percentage of which varies considerably. In view of this, engineers in the Philippines have been advised that not only is the use of salt water dangerous in concrete structures, but that beach sand and beach gravel should be employed only after having been thoroughly washed with fresh water. The foregoing, and many other similar pieces of evidence, indicate that salt and brine exert a deteriorating action on concrete.

Specification Notes.

Specifications governing concrete construction generally require that 1–2–4 concrete be used in the best class of reinforced concrete construction. In other reinforced concrete work, and in some mass concrete work, 1–3–5 concrete is specified, while in other mass work, such as dams, gravity retaining walls, etc., 1–3–6 concrete is generally required.

REINFORCED CONCRETE FOR FACTORY WORK.

One of the objections to the employment of reinforced concrete for factory work has been the difficulty experienced in attaching shaft hangers, pipe lays, and other fixtures, because on the hardness of the material. *Building Products Ltd.* (51 Columbia House, 44/46 King's Road, Chelsea, S.W. 3) claim to have solved the problem by employing standard pressed steel fittings called RIGIFIX bolt-hanger sockets and slotted inserts. These are embedded in the beams and columns of the building during course of construction. The bolt-hanger sockets are placed at fixed points to receive a ⅜-in. or ½-in. bolt. The inserts are supplied in 12 in., 18 in., and 36 in. lengths, the runway being provided with a slot to receive a ¾-in. or ⅝-in. bolt, which can be moved to any point on the length. Many modern factories have adopted these fitments.

EARTHWORK.

To determine the Volume of Earth in a Railway Cutting.

First Method.

Divide the length of the cutting into an *even* number of equal parts, and take the areas of the transverse sections at the points of division. Add together the areas of the extreme sections, twice the sum of the areas of all the intermediate sections of an *odd* order, and four times the sum of the areas of all the intermediate sections of an *even* order, and multiply by the distance between two consecutive sections; the product will be three times the volume.

Second Method.

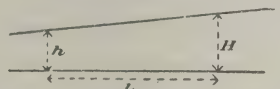

FIG. 124.

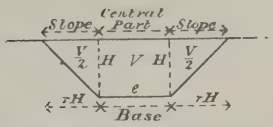

FIG. 125.

If, h = heights of section, in feet, at each end of a length, l, in feet (fig. 124).

rH = breadth of each slope at one end (fig. 125).

rh = breadth of each slope at other end.

(r = ratio of breadth of each slope to height = $\frac{\text{breadth}}{\text{height}}$).

e = base

$\frac{A}{2}$ = area of each slope at one end.

$\frac{a}{2}$ = area of each slope at other end.

V = cubic contents of both slopes = $\frac{1}{3}(A + \sqrt{A}a + a) \times l = \frac{1}{3}r(H^2 + Hh + h^2) \times l$.

V = cubic contents of centre = $\frac{1}{2}(H + h)e \times l$.

Q = cubic contents of length, l, in feet = V + V.

Third Method.

If the transverse section is on an incline, instead of horizontal, as in figs. 126 and 127, then, if A, A′, a, and a' are the respective areas of the ends of the slopes,

$$V = \tfrac{1}{6}(A + \sqrt{Aa} + a) \times l + \tfrac{1}{6}(A' + \sqrt{A'a'} + a') \times l. \qquad V = \tfrac{1}{2}(H + h)e \times l.$$

The longitudinal section of the line of railway, road, or canal, having been drawn, and the gradients laid off, the quantities of earthwork may be calculated as follows :—

If the ground is tolerably even, record the heights (or depths in cuttings) on the section at every 100 feet, or some other convenient distance. The sectional areas at each of these recorded heights (or depths) may then be calculated.

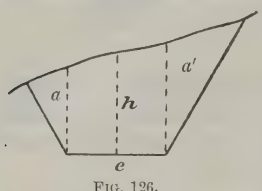

FIG. 126.

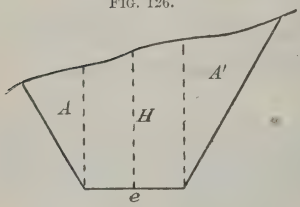

FIG. 127.

Let
A = area of section, s = s to 1 slope,
h = height or depth of section,
F = width at formation-level,

all expressed in feet ; then, if the slopes on both sides are the same, as is usually the case,

$$A = h(sh + F).$$

By this formula the areas of the first three sections of a series increasing in height regularly are calculated, and from them the remainder are at once written down by the method of second differences, as follows :

Assume heights to be 1, 2, 3, 4, 5 feet,

$$F = 10, \quad s = 2 \text{ to } 1.$$

Then

		Difference.	Second Difference.
A for 1 ft. =	12		
		16	
„ 2 „ =	28		4
		20	
„ 3 „ =	48		
		24	—
„ 4 „ =	72 ..		
		28	—
„ 5 „ =	100 ..		

and so on.

If the cross-slope of the ground is not much, and the areas of the sections do not differ very widely, the quantity of earthwork may be found by taking the mean of the two areas and multiplying by the distance between them, thus :

A′ = area of first section ; A″ = area of second section ; d = distance apart.

$$\text{Cubic contents} = d \frac{A' + A''}{2} \text{ feet.}$$

When the cross-slope is considerable, and the heights of the section differ widely, cross-sections must be taken at each place, and their areas calculated independently, and the cubic contents should then be calculated by the *First Method.*

Earthwork Tables.*

(H. R. Kempe.)

The tables on pages 482 to 487 are for the purpose of facilitating the calculation of the volumes of earthwork.

V = cubic contents, in *yards*, of both slopes.
V = cubic contents, in *yards*, of centre part.

V is calculated from the formula

$$V = \tfrac{1}{3}r(H^2 + Hh + h^2) \times l,$$

being = 1, l = 1 chain = 66 feet, and H and h being in *feet* ; so that

$$V = \tfrac{1}{3}(H^2 + Hh + h^2)\,66 \div 27 = \cdot 814815\,(H^2 + Hh + h^2) \text{ cubic yards.}$$

V is calculated from the formula

$$V = \tfrac{1}{2}(H + h)e \times l,$$

e being = 1 foot ; so that

$$V = \tfrac{1}{2}(H + h)\,66 \div 27 = 1 \cdot 22222\,(H + h) \text{ cubic yards.}$$

For any slope other than 1 to 1 the values of V in Table I. must be multiplied by r, that is by $\frac{\text{breadth of slope}}{\text{height of slope}}$. Table II. gives the values of V and V for slopes of 1 to 1½.

* Revised 1920.

EXAMPLE.—The length of a cutting is 3 chains, the width 10 feet, the $\frac{\text{breadth of slope}}{\text{height of slope}} = 2$ the height at one end 20 feet, and at the other end 15 feet; what is the cubic content of the cutting?

From table (page 483), V = 753·70, V = 42·78: then,

total cubic content = (753·70 × 2 + 42·78 × 10)3 = 5805·60 cubic yards.

Excavation.

A good excavator will dig and throw into a barrow in a day of 10 hours:

In common ground, from 8 to 10 cubic yards. In stiff clay or firm gravel, 6 cubic yards. In hard ground, where picking is required, from 3 to 5 cubic yards.

One excavator to 5 or 6 feet breadth of face of a cutting is as near as they should be.

A shoveller will throw each shovelful of earth from 6 to 10 feet horizontally, or from 4 to 5 feet vertically upwards.

PROPORTION OF EXCAVATORS, SHOVELLERS, AND WHEELERS (100 to 120 ft.).

Material.	Excavators.	Shovellers.	Wheelers.
Loose sand and vegetable moulds	0	1	1
Compact earth	½	1	1
Ordinary clay	½ to 1	1	1
Hard clay	1½ to 2	1	1

The rate at which a cutting may be expected to advance will be, for each line of wheelers or for each shoveller, in one rank:

20 cubic yards of loose sand or mould a day. 16 cubic yards of clay or compact earth a day.

EXCAVATOR MACHINES.

A modern excavator, equipped with 1½ cubic yard bucket, working in easily filled ground, can average about 600 cubic yards measured in the solid per ten-hour day when working under the most favourable conditions. In fairly stiff shale and clay 450 to 500 cubic yards. In strong ground with occasional beds of rock, 350 to 450 cubic yards. Nothing but experience will enable anyone to predict with confidence what the average daily output will be. Much larger outputs than 600 cubic yards can be obtained often for weeks together, but if at the end of the work the quantity of excavation paid for is divided by the number of shifts worked, there are not many cases where 600 cubic yards will be exceeded.

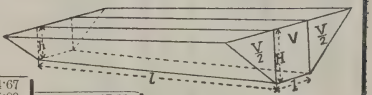
The excavating time and the estimated average daily output determine the number of machines required.

Buying second-hand excavators on large work is not advisable, unless they have done practically no work. When they are used there are always delays due to breakages, which do not occur with new machines. Steam excavators are subject to very severe shocks when at work, and unless they are in first-rate order a lot of time is lost in repairing, and worse, both foreman and driver lose interest.

It takes five men to clean up and get the machine ahead promptly; one man to look after the coal and water supply; two men putting in jumps to keep the empty waggon road close behind the machine, so that no time is lost between waggons; two horses and drivers; one or two waggon stoppers; three boys to fat waggons, turn points, and take trace chains from full to empty waggons; one foreman. Three men are required on the excavator itself—driver, fireman, and wheelsman.—(*The Engineer*, *June* 23, 1911.)

See also INDEX.

Shrinkage of Materials.



In estimating the relative amounts of excavation and embankment required, allowance must be made for difference in the spaces occupied by the material before excavation and after it is settled in embankment. The shrinkage of the different materials is about as follows:—

Gravel	8 per cent.
Gravel and sand	9 per cent.
Clay and clay earths	10 per cent.
Loam and light sandy earths	12 per cent.
Loose vegetable soil	15 per cent.
Puddled clay	25 per cent.

Rock, on the other hand, increases in volume by being broken up, and does not settle again into less than its original bulk. The increase may be taken at 50 per cent. Thus, an excavation of loam measuring 1,000 cubic yards will form only about 880 cubic yards of embankment, or an embankment of 1,000 cubic yards will require about 1,120 cubic yards measured in excavation to make it. A rock excavation measuring 1,000 cubic yards will make from 1,500 to 1,700 cubic yards of embankment, depending upon the size of the fragments.

Methods of getting Earth.

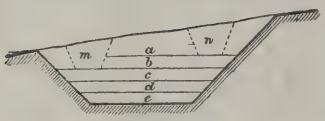

FIG. 128.

1. *Ordinary Method* (fig. 128).—Excavations carried out in layers, *a*, *b*, *c*, &c., each layer being opened out by cuts, as *m* and *n*, into which temporary ways or dobbin carts are brought. Suitable for easily-won earth and long cuttings, allowing the employment of many workmen, carts, and waggons at the same time.

2. *Method of Terracing.*—Figs. 129 and 130 show, in longitudinal section, the terraces, each of which has a transport-way, on a bench, on one or both sides of cutting, which is only removed on the completion of its terrace. Very great advantage, especially on sidelong ground, is often got by placing the temporary way alongside the cutting.

FIG. 129.

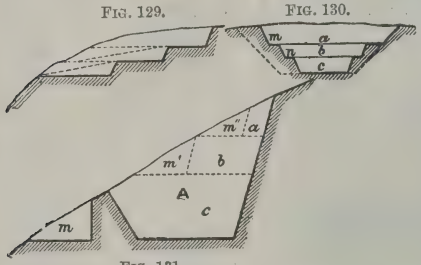

FIG. 131.

FIG. 130.

3. *Sidelong System.*—For cuttings on sidelong ground the principal temporary way runs parallel to the centre line, but at the side of cutting, which can be attacked at numerous points, and eventually along its whole length. In fig. 131, *m* represents the position of temporary way, and A the cutting. Different stages, *a*, *b*, *c*, with separate temporary ways, *m''*, *m'*, *m*, may often be advantageously employed, in which case it approximates to terracing. Steep sidelong cuttings chiefly occur in rock, where this system gives great advantages.

4. *Long-face System.*—A deep, narrow cutting, *g*, *z*, *n*, *m*, taken down to formation-level, if possible, is formed for the principal transport-way and drainage. This system is advantageous in rock strata sloping across the line, in which case the cutting will be on one side, as *m*, *n*, *p*, *o*, in fig. 132. In cases where a central cutting can be made the faces can be attacked on both sides, at different points, along the whole length, drainage and blasting being easily performed.

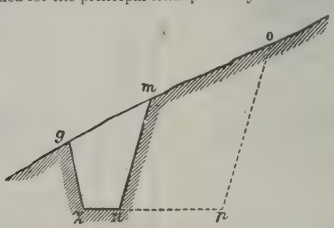

FIG. 132.

Central Lift, or English System.—A drift, *a*, *a* (figs. 133 and 134), is driven at formation-level about centre line of cutting, and a temporary way laid down in it; at the same time one or more shafts, *m*, *n*, *o*, *p*, are sunk down to it from above, and cut away in a funnel-shape, through which the stuff is shot direct into waggons standing below in the drift. This method is now widely used, with best results, both as regards time and cost. A deep cutting in lava, 500′ long × 60′ deep, containing over 124,000 cubic yards, with three shafts, was run to bank, 700′ distant, within six months, *i.e.*, at about 800 cubic yards a day. Compared with other methods it is quicker; the formation-level is at once defined; the temporary ways are shorter, and require less shifting; it is cheaper in loading waggons into which stuff falls; there is no up-throwing; and the drainage is readily done, and with the least disturbance of the work. The drift and shafts are the only source of expense, but their cost can be closely estimated.

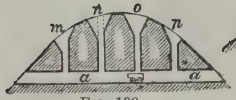

FIG. 133.

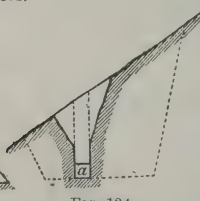

FIG. 134.

Transporting Earth.

The systems adopted comprise *barrow runs*, *horse and cart*, and *rail transport*; the latter include *hand trollies*, *horse waggons*, and *trucks drawn by locomotives or by ropes worked by stationary engines*.

Gradients in transport ways increase cost. The practical limits are: for barrows, 1 in 30; for horse and cart, 1 in 40; for temporary ways, 1 in 100.

Leading Material.

A higher up-throw, an unfavourable lifting, a repeated throwing or unnecessary moving of earth, add to cost. Good tools, well-formed barrows, carts, tip waggons, good temporary ways of rails, or planks for barrow runs, are essential. A barrow carrying 2 cubic feet without a plank run will carry 3 cubic feet with one. A tip cart carrying 8 to 10 cubic feet without, will carry 15 to 18 cubic feet with, a good temporary way.

Slopes of Excavations and Embankments.

Heights at which different soils will retain a vertical face in excavations for a short time without falling in :

	ft. ft.		ft. ft.
Clean dry sand and gravel from .	. 0 to 1	Loamy soil, well drained . .	. 5 to 10
Moist sand and ordinary surface mould	1 „ 3	Ordinary clay	. 9 „ 12

Slopes of railway cuttings are often—

In gravel, 1 to 1 when not more than 20′ deep	In clay, 2 to 1 when well drained
„ 1½ „ 1 when of greater depth	„ 3 or 4 to 1 when wet

Slopes of railway embankments are often—

In gravel, 1½ to 1 when not more than 30′ high	In clay, 2 to 1 when not more than 40′ high
„ 2 „ 1 when of greater height	„ 2½ „ 1 when of greater height

Chalk and rock will stand perpendicular, or with a slope of about ¼ base to 1 height.

In roads it is often better to make the sides of cuttings, especially on the south side, with greater slope than that they will stand at, to admit sun.

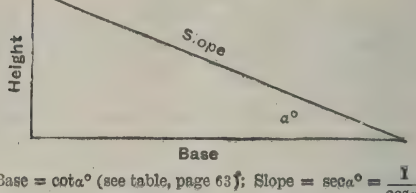
Earth in embankments should be laid in regular horizontal courses not more than 4′ thick. In high embankments they should be rather concave, to avoid slipping.

Form of Side Slopes.

The natural, strongest, and ultimate form of earth slopes is a concave curve, in which the flattest portion is at the bottom. This form is very rarely given to the slopes in constructing them ; in fact, the reverse is often the case, the slopes being made convex, thus saving excavation for the contractor, and inviting slips.

In cuttings exceeding 10 feet in depth the formation of concave slopes will materially aid in preventing slips, and in any case it will reduce the amount of material which will eventually have to be removed when cleaning up. Straight or convex slopes will continue to slip until the natural form is attained.

Table of Angles and Lengths of Slopes.



(I.)

Base of Slope is given in terms of the Height ; Length of Slope, in terms of the Base.

Angle.	Base of Slope (Height = 1).	Length of Slope (Base = 1).	Angle.	Base of Slope (Height = 1).	Length of Slope (Base = 1).	Angle.	Base of Slope (Height = 1).	Length of Slope (Base = 1).	Angle.	Base of Slope (Height = 1).	Length of Slope (Base = 1).

„ ordinary	„	$\frac{1}{20}$	„	„	$\frac{3}{40}$ „

Carting is estimated at so much per cubic yard, by the run of 1 furlong (220 yards).

Equivalents of a Load of Different Materials.

A single load of	sand, earth, rubbish	= 1 cub. yd.
„ „	lime (a measure or hundred)	= 1 cub. yd. = 21 striked bushels.
„ „	„ „ „	= 22 bushels.
„ „	squared or hewn timber, deals, &c.	= 50 cub. ft.
„ „	unhewn timber	= 40 „
„ „	bricks	= 500 bricks.
„ „	tiles	= 1,000 tiles.
„ „	water	= 1 butt of 108 gallons.
„ „	light, bulky materials	= 80 cub. ft.

Barrow and Cart Runs.

The barrows used usually hold about one-tenth cubic yard, and are mostly run on planks, which should not be narrower than 11″, and 3″ thick, nor, as a rule, have a greater inclination than 1 in 12, unless aided by ropes or winding machinery. Box-horses (fig. 135) are the best supports on an incline, either singly or resting one on another; they are mostly from 1½′ to 3′ square, made out of 11″ × 3″ planks. If a considerable height is required, trestles (fig. 136) are used, but boxhorses are stronger, and less likely to get out of repair.

A barrow run is 20 or 25 yards. Each foot of rise is considered equal to 6′ to 9′ additional run.

Wheeling is more economical than carting for distances under 100 yards.

An earth waggon holds as much as 20 or 30 wheelbarrows, and goes one-fifth faster—equal, therefore, to 24 or 36 barrows.

If loaded waggons have to be drawn up an ascent, and the temporary rails are in moderately good order, each foot of ascent may be considered equivalent to about 150 feet of additional horizontal distance.

BOXHORSE.

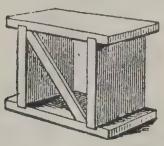

FIG. 135.

TRESTLE.

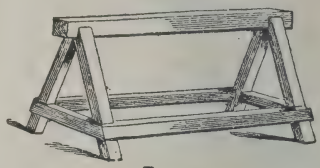

FIG. 136.

When the height exceeds 12 feet, a horse lift is better than wheeling.

For railway embankments and cuttings, locomotives are better than carting for distances over $1\frac{1}{2}$ miles.

Tip Waggons.

End Tip Waggons (figs. 137 and 138) will hold 2 yds. filled up to top of sides, as with gravel, $2\frac{1}{2}$ yds. when heaped up with clay, &c., the most economical size. The lowness of sides is of great advantage in filling.

The sides, one end, and bottom of body are of elm $1\frac{1}{2}''$ thick (the earth being confined at other end by movable tailboard), bound together with iron straps at angles, and with upright

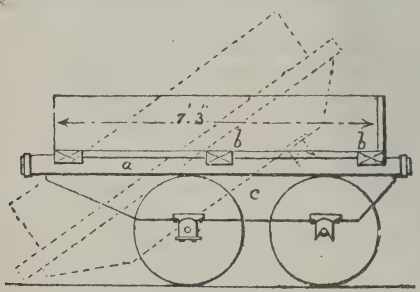

FIG. 137. Side Elevation.

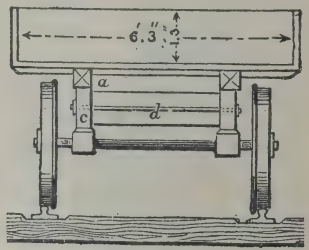

FIG. 138. Cross Section.

straps at sides and one end, all bolted through. The sole is the longitudinal piece, *a*, at each side, of elm, $5'' \times 5''$, upon which the bottom boards rest. At each end, and in middle of body, is a cross-piece of elm, *b*, $6'' \times 3''$, bolted down to the soles. The under soles, *c*, are of Memel, $12'' \times 3''$, between which from side to side are two distance-pieces, *d*, each $9'' \times 3''$, and alongside of each is a $\frac{3}{4}''$ bolt. The wheels are of cast iron, 2′ 6″ diam., with wrought-iron axles.

Weight of body of waggon, $\frac{3}{4}$ ton, of load, $3\frac{1}{4}$ tons; total load on axles, 4 tons. With well-greased axles, resistance will be about 10 lbs. per ton, but may be as high as 20. Resistance, 80 lbs. per waggon. A horse can draw 150 lbs. $2\frac{1}{2}$ miles an hour for eight hours; a horse can therefore draw two waggons.

Temporary contractor's rails weigh from 25 lbs. to 30 lbs. per yard.

It is generally better to throw earth away than to lead it three miles.

FOUNDATIONS.

In cases where there is any doubt as to the ground being of too soft a nature to bear the weight of the proposed structure, a trial pit should be sunk, or borings made with boring-rods; samples of the underlying strata may thus be brought up and examined.

Where a soft stratum overlies firm ground, the foundation should, if possible, be carried down to the firm ground; if this is not possible, piles may be driven to the solid ground and the building supported on them, or a number of piers of brickwork, masonry, or iron cylinders sunk.

Where ground is soft to a great depth, a wide trench filled with concrete may distribute the weight over a sufficiently large area to support it, or the trench may be filled with carefully rammed sand, prevented, by sheet piling or some other means, from escaping laterally. Another method is to drive a number of piles, which, by the friction of their sides, would bear the weight of the building.

Foundations on different Soils.

In any structure begun at different levels larger blocks should be used for the deeper parts, if the material admits of it, so as to reduce the number of mortar joints and the risks of unequal settlement.

With Sand or Gravel Foundation overlying Clay on a Slope, intercept water by drain on upper side of building.

Least Depth to escape Effects of Heat and Frost, from 3′ to 6′, according to climate. Not less than 3′ in England for ordinary soils, and 4′ for clay.

Rock.—Good foundation, but must be level; should be levelled, if necessary, in steps. The uneven parts should be filled up with large stones, firmly built with strong cement, or with concrete.

Gravel.—The best foundation.

Sand.—Good foundation, if dry and not liable to be washed away, but this easily occurs; drains with leaky joints may cause a subsidence, or any disturbance of the water-level in the stratum, whether by natural or artificial means, such as pumping operations connected with deep foundations, even at a great distance.

Clay.—Generally very treacherous and damp; the foundation must be deep.

Hard overlying Soft Ground.—If care is taken that the pressure per unit of area is not greater than the firm layer will bear, it may be wiser to build on it, sinking into it as little as possible.

Soft Ground overlying Hard Ground.—If the stratum of soft ground does not exceed 15′ to 20′ it will generally be cheaper to sink down to the firm ground; if not more than about 30′, drive piles or sink wells of masonry. If of indefinite depth, the platform must be supported by friction against the sides, and be therefore of considerable thickness.

Made Ground should never be trusted for the support of much weight, even though it may have lain undisturbed for years.

Load which Foundations will Bear.

Safe Load on Ordinary Foundations.

	Tons per sq. ft.		Tons per sq. ft.
1. Rock, moderately hard, strong as the strongest red brick	9·0	7. Loose beds with piling	1·82
2. Rock of the strength of good concrete	3·0	8. „ „ „ concrete	2·75
3. Rock very soft	1·8	9. Brick, stock, mortar	2·5
4. Moist clay and sand	1·36	10. „ „ Portland cement, 1 to 1	8·0
5. Coarse sand and dry clay	2·25	11. Concrete, Portland cement, 1 to 6	1·5
6. Firm stone on dry clay	3·18	12. Rubble on lias	4

Intensity of pressure on a rock foundation should at no point exceed one-eighth pressure which would crush the rock.

Buildings seldom press with a weight of more than 1 ton per square foot on foundations.

Piled Foundations.

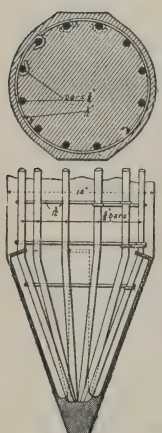

FIG. 139.

There are two kinds of piled foundations.

1. *When the soil is soft to a great depth,* area should be enclosed with sheet piling before main piles are driven, to consolidate the ground better. When the tops of the piles are connected by timber, cross-pieces (12″ × 9″ for 12″ piles) running across breadth of foundation are first notched on to heads of piles, and longitudinals, or *string pieces*, 12″ × 9″, running parallel to length of foundation, over them. On these latter, 3″ or 4″ planking (better diagonal) is laid to carry masonry. When upper stratum of ground is very soft, upper part of ground should be taken off, and filled in with stones or concrete or regular masonry. When of concrete, it should be 3′ thick for large buildings not excessively heavy.

2. *When there is hard ground below.*—In this case, as each pile resists partly by resistance to buckling as a column, the cross section should be greater in proportion to the depth. Maximum depth may be put at 30 feet. The number of piles must be proportional to weight carried.

Piles

Timber piles may be made of oak, elm, beech, larch, pine, or teak. Timber in sea-water is rapidly attacked by the wood borers *Teredo navalis* and *Limnoria terebrans*; creosoting will prevent their attack for a considerable time; it has also been suggested to cover piles with sheet copper or flat-headed copper nails. The head of the pile may be protected by a wrought-iron hoop, about 3″ × 1″, to prevent splitting when being driven. The lower end should be pointed, the length of the point being from 1½ to twice the diameter, and where the ground is hard, protected with an iron shoe. Piles protected by shoes should have a blunt end 4 to 6 inches in diameter. The shoes should have a solid point; the base being properly fitted to the blunt end of the pile prevents splitting by bolts which secure the shoes.

Concrete Piles.

Fig. 139 shows a 'Coignet' reinforced concrete pile. The reinforcement consists of longitudinal bars encircled by rings of round steel, with overlapping joints, spaced about 4 ins. apart.

For modern requirements concrete piles having a section less than 14 ins. square or equivalent area should never be used if over 30 ft. long; 12-in. square piles in many cases are quite large enough, but when it comes to actual practice it will be found that the extra cost of 14-in. piles is more than compensated for by the extra convenience of handling. The pile shoe should be of uniform taper, the faces being at an angle of about 16° to the centre-line of the pile, with nose slightly blunted. The length of the cast-iron portion to be about half the total length of the taper, the area at the top of the cast-iron point being about 40 per cent. of the sectional area of the pile in the case of the 14-in. square piles. The vertical rods to rest on the cast-iron point and to be kept in place by the recess. The straight portions of the wrought-iron arms to always be embedded in the concrete of the pile and not kept flush or project from the body.

(*W. Cleaver, paper read before Concrete Institute.*)

Piles made with a steel pipe driven to refusal and lined with concrete can develop not only the very considerable strength of the steel shell alone as an independent column, but the strength of the concrete core is materially increased by the shell acting as a continuous hooping, beside which there is an almost unlimited additional strength that can be obtained by the addition of vertical reinforcement bars. Such piles, says *Contract Record*, can endure very hard driving, can be thoroughly inspected inside, can have satisfactory bearing assured at the bottom, and can be reinforced to a high degree of strength comparable with massive structural steel columns. This reduces the number of piles and the cost of driving, and gives freedom from all uncertainty or possible deterioration from subterranean obstructions. The large factor of safety in the shell permits the safe application of working loads before the concrete filling is hard, which is often an important advantage.

Loads Carried by Piles.

A timber or steel pile is usually of the same section throughout its length, and it is then only necessary to calculate the load borne by the greatest unbraced length of the pile, regarded as a strut or column. The part below ground may be regarded as held firmly or as quite free, according to the nature of the strata. Piles are often driven so closely together, or have to be of such strength for driving purposes, that they are more than strong enough for their loads. This also applies to piles which support their loads by skin friction only and are of ample section, or numerous, in order that the area subjected to skin friction may be great enough to support the loads. But it is often necessary for the sake of economy, especially when the piles are very long, to load them up to the safe limit.

The calculations of strength may then be made as follows:

(1) If the pile is unbraced above the ground, the length measured from a few feet below the surface of the ground to the head of the pile is treated as a long column, and the section at the mid-point must be sufficient (see Column formulæ and 'Reinforced Concrete').

(2) If it is braced, the length taken is, in the case of a uniform pile, the longest unbraced length; that is, from a few feet below the ground to the point of bracing, or from the point of bracing to the head of the pile.

(3) If the pile is not uniform, the strength of the section at the mid-point of each of these lengths may have to be calculated separately, each length being treated as a long column.

(4) Bracing must not be considered effective unless it is effective in both directions, except in the following case.

(5) When the dimension of the pile is greater at right angles to the bracing than it is in the direction of the bracing, the two part lengths must be calculated as struts liable to cripple in the direction of the smaller diameter, and the whole length as a strut liable to cripple only in the direction of the larger diameter. If the formula for a square section of a reinforced concrete pile be used, the permissible load, expressed as a proportion of the short column load, may be thus modified. In each case modify the factor with l^2 in it, by multiplying by $\frac{r^2}{r_1^2}$ for the smaller dimension, and by $\frac{r^2}{r_2^2}$ for the larger dimension; where r = radius of gyration of a square section of the same area, r_1 = the smaller actual radius of gyration, and r_2 the larger actual radius of gyration. In the case of reinforced concrete piles, use the sums of the squares of the radii of gyration of the concrete and of the steel as in the formula (see 'Reinforced Concrete'). In this case the outside dimension might be the same, but the reinforcement stronger in one direction than in the other.

(6) For the portion of the pile below the ground:—

If the pile is in firm ground, or passes through a sufficient number of firm layers so that it is effectively steadied, any section of the pile should have sufficient strength, calculated as a short column; that is, it should take a load equal to the safe stress multiplied by the area. The load will be the whole load *less* an amount equal to the area of the pile above the section in question

multiplied by the coefficient of friction. This will usually range from about 1 to 4 cwts. per square foot (see ' Foundations ' under ' Bridges ').

If the ground into which the pile is driven is soft and yielding, and is not regarded as effectively steadying the pile, the strengths at mid-points of each length $l_1, l_2 \ldots$ must be calculated as those of the mid-section of a long strut or column of that length. These lengths are measured from the head of the pile, or from the point of effective bracing, to successive points in the length of the pile, the last being measured to the tip. The load in each case is the whole load less the load carried by friction on the length of pile above the point in question. Unless the tip of the pile rests on a hard stratum, or is driven some way into a very firm stratum, the load vanishes before the point is reached, and very few calculations will actually be required.

(7) If the pile so rests upon a firm stratum that a large part of the load is carried from the lower end, the same procedure may be adopted, but the loads will, of course, be greater.

If the length of the pile below ground is small, and it is driven into or rests on a hard stratum, the whole length may have to be calculated as a strut carrying the whole load. Such length as is actually in firm ground should, however, be subtracted from the length for calculation.

In some cases the support given by the ground may not be regarded as equivalent to effective bracing, but may be considerable. The strength of any section may then be calculated in the first place as though the soil were quite firm and hard, giving a load W_1, and next as though the soil, though exerting the effect of skin friction, had no bracing effect, giving a load W_2. The actual load will be something between W_1 and W_2, depending upon the estimated value of the soil as a steadier of the pile. Even soft silt must be regarded as exerting a considerable steadying effect; but if there be progressive movement of silt, sand, or peaty ground, no steadying effect can be counted upon. Considerable movement, of course, demands the provision of special bracing, or, with short piles driven into a firm stratum, the calculation of a cantilever effect based upon the observed pressure as recorded by a torsion pressure meter or otherwise estimated.

Generally: to find the necessary strength at any section S, measure the distance upwards to the head or bracing, at A, and an equal distance downwards to a point B. Calculate the load P carried by skin friction above B, and (W—P) is the load carried by A B as a strut. The strength at S will be calculated as that of a short strut if most of the length B S be effectively steadied by the ground; if there be no such steadying the calculation will be that for a strut of length A B (but in no case any greater length). If the lower half of S B is in firm ground, or all of it in weak ground, the section may be calculated for a stress somewhere between that allowable as a short strut and that allowable on the length A B as a free strut.

The strength of the cross-sections of a pile does not change suddenly, and very few calculations need be made in actual practice; but any of the above may be necessary in a particular case.

The two most probable errors are, first, to calculate as free struts lengths which are really steadied by the ground, and secondly, to neglect making for each section the reduction of load (regarding the section as the mid-point of a strut) due to skin friction from the surface of the ground to a point which is as far below the section as the bracing or head of the pile is above it. The load which the length in question itself carries by skin friction is imposed, upwards, upon some other mid-section nearer the head of the pile.

Loads on Reinforced Concrete Piles.

A well-designed reinforced concrete pile, 14 ins. by 14 ins. in section, will carry a load up to 100 tons (calculated). In actual practice such piles are carrying loads of 60 to 70 tons (at Bristol up to 65 tons; in the Thames, 15-in. × 15-in. piles, 70 tons).

The 'Simplex' System of Piling.

A cast-iron point is first driven to the required depth by means of a 16-inch steel pipe, ⅜ inch or ½ inch in thickness, stiffened with a collar at the top. The pipe is then filled with concrete and afterwards withdrawn slowly, the concrete filling adapting itself to irregularities in the ground. When more than one length of pipe is needed, welded joints may be preferred to riveted joints with cover plates. Instead of the permanent point or shoe an ' alligator ' pile point may be used, consisting of a sleeve of annealed cast steel, about 17 ins. in diameter, and a pair of toothed jaws hinged to the sleeve in such a manner that when closed they form a flat cutting edge which penetrates the ground. When the pipe is drawn up a foot or more the jaws open, allowing the concrete to pass through to the bottom of the hole.

Pile-sinking with the Water Jet.

In sinking piles the work may sometimes be much facilitated by the use of a water jet. In the case of hollow piles, the usual shoe may be replaced by a funnel-shaped end-piece, and the water pumped through the pile. In sinking cast-iron piles for bridge piers in New South Wales (*E. M. de Burgh*) it was found that a central nozzle with an aperture of 2 ins., and four holes of ½ diameter in the conical portion, gave good results in sand and soft clay, the piles being sunk through 14 ft. of sand in an average time of 6 minutes, and the actual rate of movement was about 8 ft. a minute. For sinking in sand not under water it was found expedient to flood the surface round the pile. For clay, the pile was loaded with ten tons, and after 5 or 10 minutes

pumping the pile would sink 6 to 9 ins. At a depth of 11 ft. in the clay, progress was very slow, and practically ceased at 13 ft., with the 10-ton load. These piles had flanged joints.

Timber piles can be similarly sunk, the pipe being taken down the side of the pile. On the work referred to above, timber piles, 14 ins. in diameter at one end and 9 ins. at the other, were sunk 16 ft. on an average; the average time taken being 4 minutes, and the water pressure 5 to 7 lbs. per sq. in. in sand and 30 to 40 lbs. per sq. in. in clay. The pipe (2-in.) was taken to a $1\frac{3}{4}$-in. augur hole in the point of the pile.

In driving steel sheet piling at Hodbarrow (*H. S. Bidwell*) a water jet was used in hard ground. Double ram pumps $5\frac{1}{2}$ ins. and 6 ins. in diameter were used, with 10 to 14 h.p. boiler capacity, the water being delivered by a 5-in. pipe, diminishing to 3-in. and to $1\frac{1}{2}$-in. From this a $1\frac{1}{4}$-in. vertical pipe led to two $\frac{3}{4}$-in. jets. The jet pipes were kept working up and down, with a block and tackle, about level with or slightly below the point of the pile. After three or four tides, the ground had recovered its normal consistency.

Piling Hammers.

Single Semi-Automatic Direct-Acting Steam Piling-Hammers.

(*The British Steel Piling Co.*)

This type of hammer, which is suitable for every description of pile driving, consists of a cylinder of cast iron raised by steam pressure and allowed to fall through gravity on the pile. The steam is admitted to the cylinder through a hollow piston rod by means of a piston valve, worked by a lever, at the upper end of this rod; steam being led to the valve by a flexible tube. The lower end of the piston rod, which is solid, passes through the bottom end of the cylinder, whilst the piston is between, the whole being made of one steel forging drawn down from an ingot and bored from the solid. The piston is fitted with rings, whilst the ports are placed on the upper face of same and lead into the hollow piston rod. When the lever is pulled down, it allows the steam to pass down this hollow rod through the ports into the cylinder, when the cylinder immediately rises, the pressure being between the piston and the cover. As soon as the cylinder is raised to the required height, the lever is released and the piston in the valve forced back to the exhaust position, thus cutting off the incoming steam and allowing the steam in the cylinder to escape to the atmosphere. When the operation is repeated the pistons in the valve, having differential areas, the tendency is always to keep the valve at the exhaust position. The piston valve is of very heavy pattern and made of gun-metal throughout, and fitted with phosphor-bronze piston rings. These hammers are so simple in their construction, and so strongly built, that spare parts are rarely required. They do not wet the top of the pile and cannot overrun their stroke owing to a safety hole, placed in the lower end of the cylinder; whilst the whole weight of the hammer is always on the pile. The exhaust is particularly free, so that there is practically no cushioning in the cylinder and consequent loss of blow. One man can easily operate the hammer and maintain a speed of 50 to 60 blows per minute continuously. These hammers are made in sizes from 10 cwts. to 5 tons.

The McKiernan-Terry Patent Double-Acting Automatic Pile-Hammers.

With these hammers 90 lbs. pressure gives a striking blow of 7,800 ft.-lbs. per min., at 140 strokes per min. A 40 h.p. boiler is required. The net weight of the hammer is 6,800 lbs., and the cylinder stroke 16 ins.

Safe Load on Piles.

Rankine gives safe load on piles as follows:—
For piles driven till they reach firm ground, 1,000 lbs. per square inch of area of head.
For piles standing in soft ground, by friction, 200 lbs. per square inch of area of head.

Formulæ for Safe Load on Piles.

(1.)

If P = safe-load on a pile; h = height of fall in feet;
w = weight of ram; s = penetration per blow in inches;
(P and w must be in the same units—i.e. both in lbs. or both in tons, for example),

$$P = \frac{2wh}{s+1}$$

(2.)

If P = safe load on pile; a = sectional area of pile;
w = weight of ram; E = modulus of elasticity;
h = height of fall; x = weight of pile;
s = depth driven by last blow; l = length of pile.

Rankine's formula,

$$P = \sqrt{\left(\frac{4Eawh}{l^2} + \frac{4E^2a^2s^2}{l}\right)} - \frac{2Eas}{l}.$$

Sanders' formula,

$$P = \frac{wh}{8s}.$$

Weisbach's formula, $$P = \frac{w^2 h}{s(w + x)}.$$

In Rankine's formula the safe load is taken to be about $\frac{1}{3}$ of the greatest load; if there is a great vibration, the factor of safety should be increased to 8 or 9; where there is no vibration, a factor of safety of 3 or even less may be adopted.

'Engineering News' (U.S.A.) formula, $$P = \frac{fwh}{p + 1}.$$

Where p is the average penetration in the last six blows; f a factor ranging from 1 to 12, and recommended to be taken as 2.

Screw Piles.

Screw Piles, figs. 140 and 141, are either of wood or of cast or wrought iron; they are seldom less than 6, or more than 18 inches, in diameter. They should be cylindrical in section to enable them to be more readily turned. They are fitted with a screw disc at the foot of the pile, similar to an auger, which usually does not make more than one and a half turns. This disc is of cast-iron, which is made up to 6 feet in diameter. The piles are usually sunk by manual power acting on long levers fixed to a capstan head on the piles, so as to screw them down to a firm stratum. When screw piles have to be sunk through hard ground, a water jet may be used to facilitate sinking.

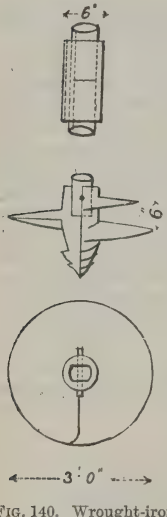

FIG. 140. Wrought-iron pile with cast-iron disc.

Cylinders.

Cylinders of cast-iron are sunk to a firm foundation by excavating inside and letting them sink by their own weight, or if that is not sufficient, adding additional weight. As the cylinder sinks, lengths are bolted on by means of flanges which are on the inside. When it is desirable to make the joints water-tight, a cloth strip saturated with thick paint is laid between the flanges.

Small cylinders from 4 to 10 feet in diameter are usually cast in lengths of from 5 to 10 feet, without any vertical joint, and from 1 to $1\frac{1}{2}$ inches in thickness with $1\frac{3}{4}$ or 2 inch internal flanges. The thickness in inches necessary to withstand the pressure of the water of small thin cylinders may be approximately found from the formula—

$$t = \cdot 001\, rh\ ;$$

where r is the radius of cylinder, and h depth of water, both in feet, and assuming that the metal will stand with safety a compression of 5,000 lbs. per square inch. In no case should the thickness t be less than $\frac{1}{4}$ inch. The inside of the cylinder is excavated by hand, or if the water cannot be kept out, by means of a grab, and is afterwards filled up with concrete or masonry.

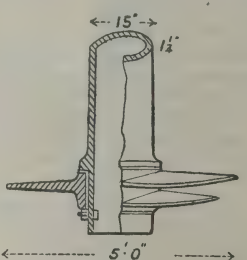

FIG. 141.—Cast-iron pile and disc.

At the St. Louis Bridge, U.S.A., the cylinders were 4, 6, and 8 feet, in diameter, cast in 10-feet lengths, the metal being $1\frac{1}{4}$ inch thick with $2\frac{3}{4}$-inch flanges.

The bottom cylinder of the Albert Bridge over the Thames was 21 feet in diameter and 4 feet 6 inches high, cast in one piece; on this was a reducing ring tapering to 15 feet in diameter; all the other rings were 15 feet in diameter and 6 feet high, also cast in one piece.

Brick or masonry cylinders built on an iron or wooden curb are frequently used instead of iron cylinders.

Pneumatic Process of Sinking Cylinders.

Cylinders and large caissons are often sunk by the pneumatic process. The cylinder is made as nearly as possible air-tight, and an air-lock or chamber, with two doors, one opening from the outer air and the other into the cylinder, is bolted on to it; both of these doors open downwards into the cylinder or against the pressure of the air. Air is pumped into the cylinder so as to drive the water out. The workmen then enter the air lock, the door communicating with the outer air is closed, and the compressed air allowed to enter from the cylinder; when the pressure has become equal the door into the cylinder is opened and the workmen descend. The excavated material is carried up through the air lock, or blown up through a tube by air pressure. The cylinder is buoyed up by the pressure of the air inside it, and when this is released it tends to sink. It has generally been considered that men cannot work in safety under a greater depth of

water than 100 ft.; in the St. Louis Bridge 108 ft. was reached, and 147 ft. under mean low water is said to have been attained in the East River Gas Company's tunnel at New York.

Steel Sheet Piling.

BRITISH PRACTICE.

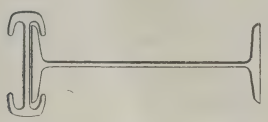

FIG. 141A.—Universal Joist Section.

British standard joists are employed, having flanges 5 ins. wide and used in conjunction with a standard clutch or locking bar. The ranges of joists are 15 ins. by 5 ins., 12 ins. by 5 ins., 10 ins. by 5 ins., 8 ins. by 5 ins. and 6 ins. by 5 ins. The clutch is put on the flange of joist at works and the two driven as one. The section has great strength, and is very easily straightened for re-use and possesses high salvage value, as the joists can be used for constructional purposes. Supplied up to 65 ft. lengths.

Simplex Section, 12 ft.; 26·5 lbs. per sup. ft. Simplex Section, 8 ft.; 22 lbs. per sup. ft.

FIG. 141B.

These sections consist of one member only and are used for lighter forms of construction. They can be obtained in lengths up to 40 ft.

With double-acting hammers, the cost of driving steel sheet piling, as against timber, is usually about one-fourth, and frequently as low as one-twentieth. In a recent example, a No. 6 double-acting hammer (McKiernan-Terry), at Larne, drove 845 12-in. 'Simplex' piles, in lengths varying from 33 ft. to 15 ft., in seventeen working days.

RANSOME INTERLOCKING TYPE 'D' STEEL SHEET PILING.

(*Ransome Machinery Co.* (1920) *Ltd., London.*)

Section.	Weight per ft. run.	Moment of Inertia.	Section Modulus.	Radius of Gyration.	Weight per sq. ft. interlocked.
D	33 lbs.	10·595 ins.⁴	7·0633 ins.³	1·058 ins.	28 lbs.

This section is made in single lengths up to 60 ft., and can be used for irregular areas.
Covering capacity, 80 sq. ft. per ton.

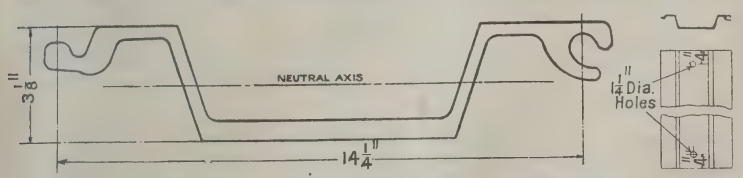

FIG. 141C.—Ransome Interlocking Type 'D' Steel Sheet Piling.

T

This section (fig. 141C) is claimed to be the strongest British piling in proportion to its weight per sq. ft., the strength being due to the trough-shape, with a neutral axis running through the centre of the pile, as shown in the figure.

The interlock is water-tight, without clay puddling, and it is sufficiently flexible to enable circular cofferdams to be built as small as 5 ft. 3 ins. in diameter, without using special piles. The safe working stress is 16,000 lbs. per sq. in.

The advantage claimed for this piling is that, in view of its large covering capaci y in proportion to its weight, one-third less tons of the piling are required to cover a given area, so that about one-third less has, consequently, to be paid for freightage.

The piling is made of special toughened steel that penetrates the hardest ground without damage to the piling. It is specially easy to drive and extract with Ransome plant, and can be used repeatedly.

Some of the classes of work for which Ransome type 'D' Piling is used are cofferdams, caissons, dams, retaining walls, lock, dock, harbour, breakwater, canal and reservoir work, bridge and other foundations, shaft-sinking, etc.

'SIDE-GROOVE' STEEL PILING.

(Side-Groove Steel Piling Supply Co., Ltd., London.)

These sections (figs. 141D and 141E), known as 'Side-Groove' Steel Piling (Annison's Patents), have an independent locking bar of heavy design and consequent great tensional strength in the joints of the assembled piles. The bars are slid on to the sheet members at the mills before dispatch, so that one bar and sheet are driven together as one pile. Thus assembled they form the widest steel piling manufactured: time and cost in driving them is therefore comparatively low. These sections are very adaptable, and special piles, such as corner pieces, etc., can be readily manufactured for any class of work. The heavier types can be rolled in lengths up to 61 ft., and the lighter type up to 40 ft.

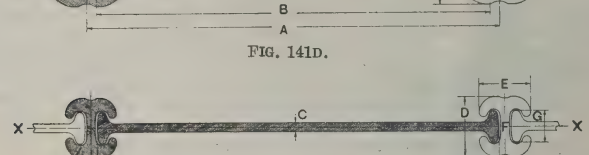

FIG. 141D.

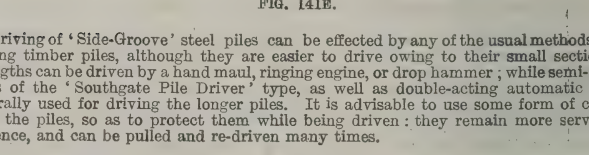

FIG. 141E.

The driving of 'Side-Groove' steel piles can be effected by any of the usual methods practised for driving timber piles, although they are easier to drive owing to their small sectional area. Short lengths can be driven by a hand maul, ringing engine, or drop hammer; while semi-automatic hammers of the 'Southgate Pile Driver' type, as well as double-acting automatic hammers, are generally used for driving the longer piles. It is advisable to use some form of cap on the heads of the piles, so as to protect them while being driven: they remain more serviceable in consequence, and can be pulled and re-driven many times.

DIMENSIONS AND WEIGHTS OF 'SIDE-GROOVE' STEEL PILING.

'Side-Groove' Steel Piling.	Dimensions.							Weight per Super. Foot Assembled.
	A	B	C	D	E	F	G	
	Ins.	Ins.	Ins.	Ins.	Ins.	Ins.	Ins.	Lbs.
Heavy section	$21\frac{3}{4}$	$20\frac{5}{8}$	$\frac{13}{16}$	$4\frac{5}{8}$	$4\frac{1}{8}$	$\frac{3}{4}$	$2\frac{3}{8}$	41·65
" "	$21\frac{3}{4}$	$20\frac{5}{8}$	$\frac{1}{2}$	$4\frac{5}{8}$	$4\frac{1}{2}$	$\frac{3}{4}$	$2\frac{15}{16}$	45·28
Light section	$21\frac{3}{4}$	21	$\frac{15}{32}$	$2\frac{7}{8}$	$2\frac{15}{32}$	$\frac{13}{32}$	$1\frac{1}{4}$	25 approx.

AMERICAN PRACTICE.

The following are three principal varieties. In the first form, (*a*), (*b*), and (*c*), fig. 141F, the section is symmetrical with respect to a longitudinal axis, but unsymmetrical with respect to a transverse axis. In the second form, (*a*) and (*b*), fig. 141G, the reverse is the case. In the third

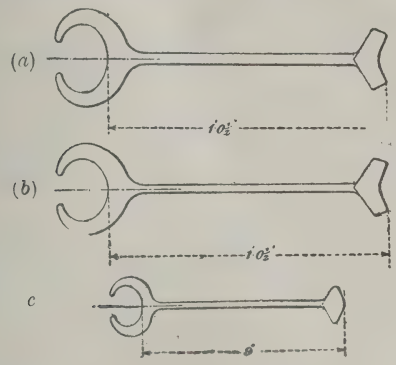

FIG. 141F.

form, either of the two pieces together form a unit symmetrical to both axes. All the forms may be used over and over again as steel sheet piles.

Sheet piles of the rolled forms may be secured from the mills in lengths up to 45 ft. for one or two light sections and up to 70 ft., or perhaps more, for other weights.

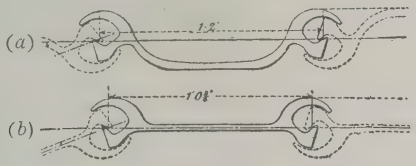

FIG. 141G.

In fig. 141H is shown a simple steel plate bent round a vertical axle of curvature and given suitable interlocking hooks at the sides. The curvature adds to the rigidity. This piling is assembled with concavities and convexities alternating.

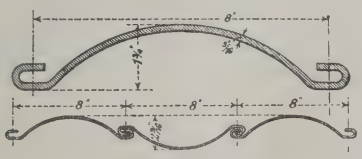

FIG 141H.

Another type of steel-plate sheet piling has vertica corrugations, such as shown in fig. 141 I. These corrugations are made on radii of curvature of but an inch or so. The interlock is made by overlapping edges and securing one or both by vertical straps riveted on to the piling. Sometimes the straps are not continuous, but are broken up into short and separated lengths. In driving piling of these classes it is usual to hammer shut the interlock opening on the

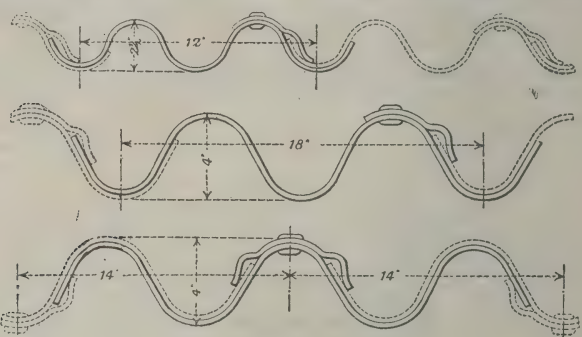

FIG. 141 I.

forward side at the bottom of the pile about to be driven. This tends to prevent rupture or distortion and to keep the interlock clear. When the next pile goes down it opens out the inter-locking space. The first two rolled forms are obtainable with $\frac{1}{4}$-in. webs. The second form is now obtainable with a web thickness of $\frac{7}{32}$ in. Plate steel sheet piling is obtainable in still thinner metal.

Driving.

The driving of the steel sheeting is generally effected by means of double-acting pile hammers, the McKiernan-Terry being a usual type. The blows are given in rapid succession.

Light-weight sheeting, and also heavy piling, may at times be very advantageously driven with a water jet. Such material as mud, soft clay, and clear sand will ordinarily respond to the jet. If, however, the material is hard clay or a sand containing a heavy percentage of gravel, the water jet is an inadvisable adjunct. A supply pipe of 1 in. diameter and a $\frac{3}{4}$-in. nozzle will be suitable for moderate weights of piling having a width of, say, 13 ins. or less.

Pulling.

It is quite customary to pull piles that have been used in temporary service. The cost of pulling is considerable. While, in general, it is not as great as the cost of driving, still it is to be rated as equal to a large percentage of the expense of driving the very same piles which it is proposed to pull out again. This percentage may rise as high as 75, or even higher. Where the piling has been driven with a wooden maul, or could have been so driven, a simple lever may suffice. This lever may have attached to it metal straps or other devices to facilitate connecting the pile head with the lever. Simple perforations in the top of the pile serve for the introduction of bolts or pins. Ordinary hoisting arrangements may suffice for these piles and for still heavier sheeting. Hydraulic jacks have been used for rather difficult pulling. The jacks may be used mainly for starting the units. By setting up jacks on the heads of the adjacent piles they may be brought to bear beneath a head block provided with a slot through which the intermediate pile may pass on its way up. Another method that has been used simply sets up a framework provided with a strong cross-piece, to which blocks and tackle may be rigged. The line may be operated by hand or by power, as circumstances may require. For pulling piles which had been put down to a considerable depth, a percussion-piston pile-driving hammer was hung upside down from a derrick boom and used thus to pull the piles. In pulling, the inverted hammer takes hold of the pile by means of the shackle, and steady tension is then exerted on the pile line, which pulls the shackle strap down upon the anvil block, and the hammer is placed in operation. Piles of 26 ft. penetration in clay, sand, and gravel were withdrawn in from 2 minutes to 10 minutes each, without distortion. The McKiernan-Terry pile hammers can also be used for pulling purposes.

Cost Data.

The following are the cost data relating to the driving of 19,654 lineal feet of 12-in. rolled piling of the first type.

The piling weighed 40 lbs. per lineal foot. The material penetrated was sand and clay, and the piles varied in length from 40 ft. to 60 ft. Twenty-one working days of 10 hours each were

consumed on the work. Maintenance and operation are put at $7 per day. Nine men, including a foreman, an engineer, and a fireman, constituted the crew. Their combined daily wage amounted to $28·50. The expense for 21 days, including a $60 item for handling and incidentals, totalled $805·50. The total cost per foot of penetration is given as $0·041. Estimated on the basis of the weight driven, the cost was $2·05 per ton of 2,000 lbs.

Caissons.

Very deep and large piers and abutments of bridges have recently been constructed with steel caissons braced internally so as to prevent them collapsing while sinking. These caissons are excavated and filled with concrete or masonry.

The foundations of the Hawksbury Bridge in Australia were sunk to a depth of 162 feet below high-water level by dredging.

Frictional Resistance of Pneumatic Foundations (Schmott).

The foundation must be vertical, being kept in equilibrium by the friction of its surface.

According to Mr. F. W. Sweeney in the *Journal of the Western Society of Engineers*, experience in sinking concrete caissons for bridge foundations has shown that building the walls with a batter is not only of no particular advantage in reducing the sinking friction, but it is positively detrimental to the proper guiding of the caisson. It is considered the best practice to have a perfectly plumb wall. When the depth of water will permit, it is generally cheaper to build up a river caisson on shore in the form of a wooden shell, launch it, tow it into position between guide piles and sink it by filling with concrete.

Freezing Process of Sinking Foundations.

The Freezing Process has been used to sink large foundations in treacherous material, especially quicksand. Pipes 10-inch in diameter, open at the bottom, are sunk vertically about 3 feet apart round the ground to be excavated; inside of these 8-inch pipes, closed at the bottom, are lowered, and again within the latter small pipes. The freezing material is pumped into the smaller pipes, and returns to the cooling tank through the large ones. A solid cylinder of frozen ground is gradually formed round the pipes; these frozen cylinders unite, forming a solid ring round the place to be excavated. The material to be removed will, of course, be frozen solid, and therefore much more difficult to excavate.

Dams.

If the depth of the water does not exceed 4 feet, the bottom moderately firm, and there is no current, a dam of clay puddle about 3 feet wide on top may be formed round the space to be enclosed: before the dam is commenced care should be taken to remove all loose porous material and roots from the site, and, if possible, excavate a trench for its foundation. Long lengths of waterproof canvas, sewn together and weighted with a chain stitched to the ends so as to keep it in place, have also been used. The canvas should be supported by a framework of timber (see fig. 142). These frameworks are spaced about 8 feet apart and sheeted with boarding between. The ground should be dredged level to receive them.

Puddle Dams.

Coffer dams of puddle usually consist of two parallel rows of sheet piling, the intervening space between them being filled in with puddle; sometimes three or even four rows, with a puddle wall between each, have been adopted in order to give greater stability and make the dam more watertight.

It is always desirable to make the puddle wall as thin as possible; it is seldom more than

4½ or 5 feet in thickness. Bolts through coffer dams should be avoided as far as possible, as the puddle in settling leaves vacant spaces along them, causing leaks; to remedy this, iron discs through which they pass have been used; these discs are embedded midway in the puddle wall.

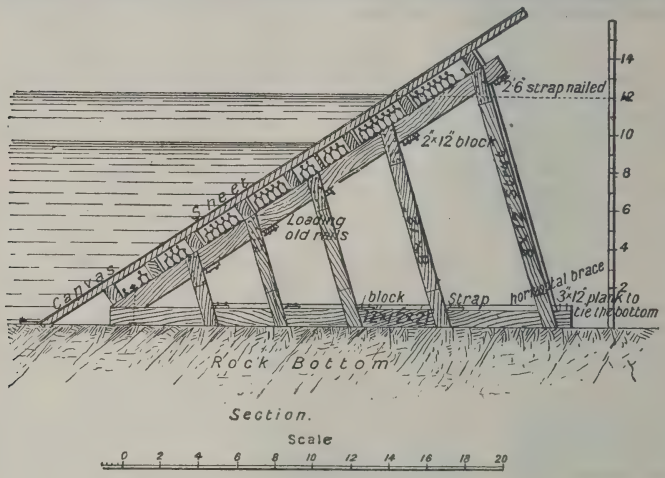

FIG. 142.

In coffer dams made for the construction of the East London Railway through the docks, through bolts were entirely dispensed with, their place being taken by buttress piles driven at intervals on the outside which withstood the pressure of the puddle.

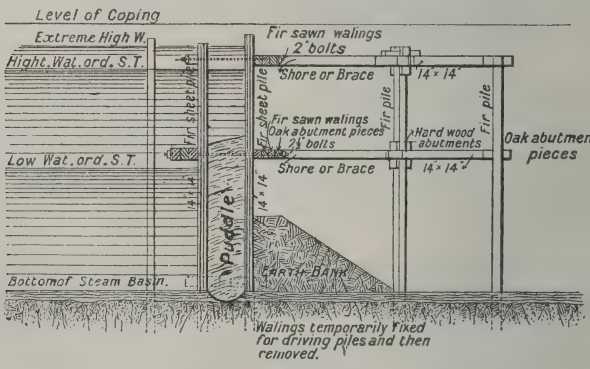

FIG. 143.

Fig. 143 shows a coffer dam used at Portsmouth Dockyard extension. The shoring piles were driven 9 feet centre to centre, and 12-inch by 12-inch struts, one horizontal and one inclined were fixed to each.

Puddle should be free from large stones, roots and vegetable matter liable to decay. Some engineers consider a certain amount of sand or gravel renders it less liable to crack.

Single Balk Dams.

Dams have also been most successfully constructed of single rows of sheet piling grooved and driven between waling pieces. Fig. 143A is the more usual arrangement; the piles are from 9 to 12 inches in thickness; a groove about 2 inches wide and 2 inches deep is cut out of each

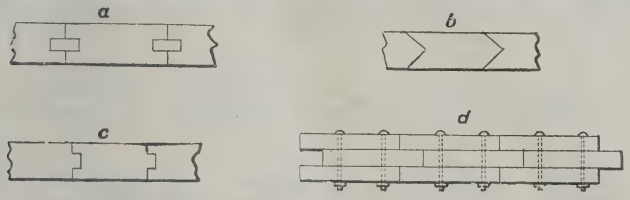

Fig. 143A.

pile; into this is fitted a tongue, which is cut to the exact size to fit it. Sheet piles should be sawn die-square with the grooves perfectly straight and true. They should be of sufficient thickness to withstand the water pressure without bulging between the waling pieces. Small leaks at the joints may be stopped by caulking with oakum.

Cribs.

Timber cribs or boxes, which are usually made watertight and floated into position and then sunk, have been largely used in America for foundations of bridges on rock, or in places where there is no fear of undermining by the currents. They are filled with concrete.

Scaffolding.

Standards are upright poles, generally of spruce, 20′ to 50′ long, 5″ to 8″ diam. at butt; those under 2½″ at tips are termed *rickers*, and run about 22′ long. They are firmly fixed in the ground (or in tubs filled with earth, if excavation is inconvenient), 4′ 6″ from wall, 10′ to 12′ apart. When greater lengths are required, two are lashed together, tip to butt, and tightened with wedges. To these, on the side next the wall, are lashed horizontal *ledgers*, or *runners*, parallel to the wall at vertical intervals of 3′ 6″ to 5′. They support the *putlogs*, of squared timber (usually birch), 4″ × 3″, 6′ long, one end of which rests on the ledgers, the other in a hole in the wall left by omitting a brick header; they are about 3½′ or 4′ apart, and support the *scaffold boards*, usually 9″ × 1½″, sometimes 3″. Poles called 'braces,' lashed diagonally across every three or four standards, stiffen the scaffold. Masons often use a second row of standards and runners, close to the wall, to prevent the masonry being disfigured by putlog holes.

Fig. 144 (from Spon's 'Dict. of Eng.') shows the arrangement of a bricklayer's scaffold. When the scaffold has to be carried to a considerable height, other poles are lashed to the standards with ropes tightened by wedges. Poles are also lashed diagonally across every three or four standards in the shape of a St. Andrew's cross; these are called braces, and they serve to stiffen or brace the scaffold longitudinally.

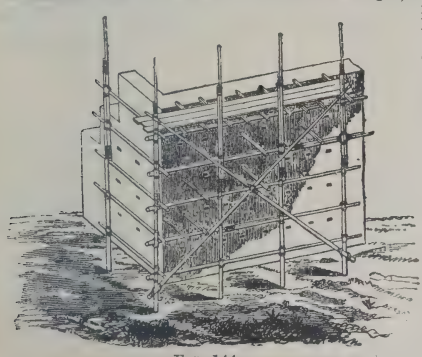

Fig. 144.

In buildings which do not admit of putlog holes in the walls, as where rubble stone or ashlar facing is used, and which do not require heavy machinery for hoisting, or strong timbers in the scaffold, two rows of standards with ledgers are used, one row being close to the wall, and the other at the usual distance, so that both ends of the putlogs may rest on the ledgers. Scaffolds such as we have just described are sometimes used for heights of 90′ or 100′ from the ground, as in building church steeples and similar work. In the erection of houses it is usual to construct a staging about 10′ square on the outside of the scaffolding, for the purpose of hoisting materials, and from which they are distributed for use.

This staging is usually formed with standards and ledgers in the same manner as the scaffold to which it is connected.

Scaffolding Knots.

The principles of a good knot are its facility in tying, its freedom from slipping, and its being easily untied. All knots will jam more or less when subject to a strain. The knots in fig. 144A are shown open before being drawn taut, in order to show the position of the parts. The names usually given, and their uses, are as follows :—

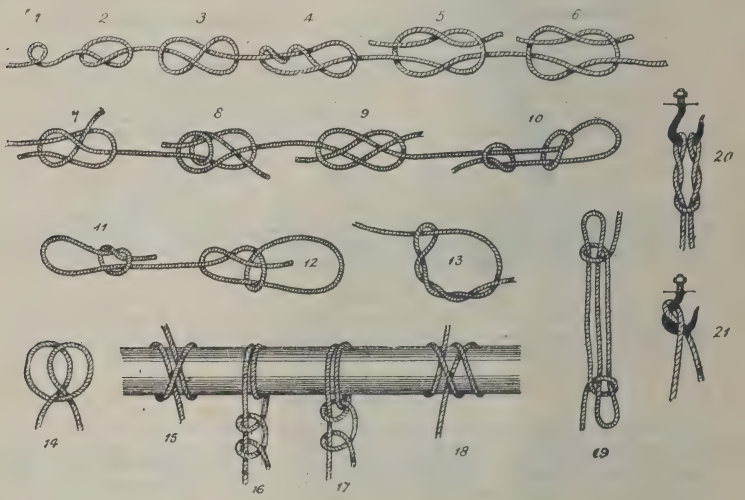

FIG. 144A.

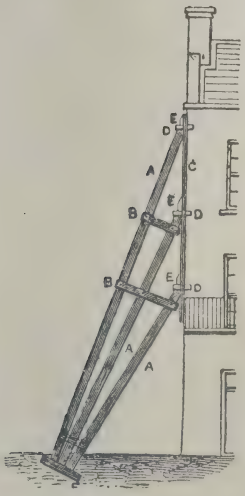
1. Bight of a rope.
2. Overhand, or thumb, knot, to prevent a rope running through the sheave of a block.
3. Figure of eight knot, used as No. 2.
4. Stevedore knot : is useful when the rope passes through an eye. It is easily untied after being strained.
5. Square, or reef, knot. This is a most useful knot for joining two ropes of same size. However tight it jams, it is easily 'upset' and undone.
6. Granny, or thief, knot. This should not be used, as it will jam tight but not slip (as erroneously supposed), will not 'upset,' and consequently is difficult to undo.
7. Single sheet bend, or weavers' knot, used principally for joining two ropes of unequal sizes more securely than a reef knot.
8. Double sheet bend, more secure than No. 7.
9. Carrick bend, for fastening the four guys to a derrick.
10. Flemish loop.
11. Slip knot.
12. Bowline, for making a loop that will not slip. After being strained, this knot is easily untied. Commence by making a bight in the rope, then put the end through the bight and under the standing part, pass the end again through the bight, and pull taut. This knot should be tied with facility by everyone who handles ropes.
13. Timber hitch ; the greater the strain the tighter it will hold.
14. Clove hitch, consisting of two half-hitches ; used chiefly to tie ledgers to standards. This is the most useful of all the knots used in scaffolding, on account of its simplicity and security.
15. Clove hitch, as No. 14, showing its application around a pole.
16. Round turn and two half-hitches, for securing a rope to a ledger or for fastening the guys of derricks, shear legs, &c.
17. Fisherman's bend, used when a thick rope, such as a fall, is made fast to a ring.
18. Rolling hitch, used in a variety of ways, chiefly in making fast one rope to another that is held taut.
19. Sheepshank, for shortening a rope when the ends are inaccessible.
20. Catspaw. An endless loop, and used where great power is required.
21. Blackwaller. Easily applied, but requires watching ; has a tendency to slip.

Shoring Buildings.

A plank (fig. 151), C, 9 ins. wide, 3 ins. thick, the length varying with height of building, is placed against upper part of wall to be supported. In this rectangular holes are cut to admit of timber 'needles,' D, from 4 ins. × 6 ins. × 6 ins., and about 12 ins. long. These are let into



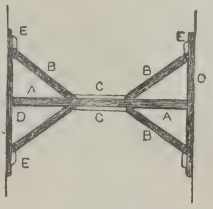


FIG. 151.

FIG. 152.

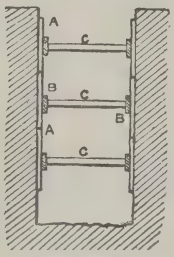

FIG. 153.

the wall about 4½ ins., and project beyond the plank about 4½ ins. to receive the ends of the 'shores,' A.

A cleat, E, is usually nailed to the plank on the upper side of each needle.

The struts, A, are from 6 ins. × 4 ins. in very small buildings to 12 ins. × 9 ins. or 12 ins. in very large; usually half timbers 12 ins. × 6 ins. They are fixed to a footing block, F.

The outer strut is called a 'top raker,' the inner the 'bottom shore,' the centre the 'middle raker.'

Short pieces, B, about 1 in. thick and from 6 ins. to 9 ins. wide are nailed on each side of the shores.

Struts between Houses.

A (fig. 152), horizontal strut, 6 ins. × 4 ins. to 9 ins. × 4 ins.
B, raking strut, 6 ins. × 4 ins.
C, straining-piece, 6 ins. × 3 ins.
D, plank, 9 ins. × 3 ins.
E, cleats.

The horizontal strut, A, is at height above ground equal to about two-thirds height from ground to eaves.

Timbering Trenches.

A (fig. 153), poling boards, about 3 ft. long, 1 in. to 1½ in. thick, 7 ins. to 9 ins. wide, placed against the side as each successive depth of 3 ft. is excavated.

B, waling planks, 9 ins. × 3 ins., placed longitudinally against the centre of each row of poling boards.

C, struts from 4 ins. square to 6 ins. or 8 ins. square, according to their length and the pressure. Raking pieces are added in bad ground.

RETAINING-WALLS

Pressure of Earth.

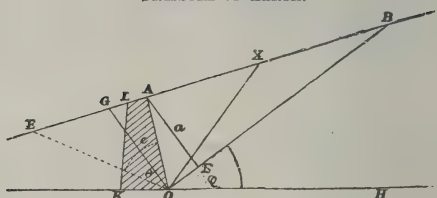

Fig. 153A.

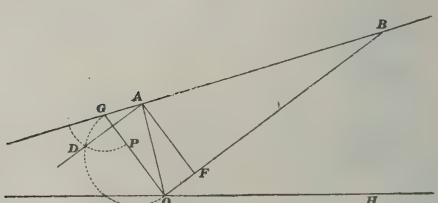

Fig. 153B.

Let AB, fig. 153A, be the surface of the ground, and OB the natural slope at an angle ϕ.

Draw OE, making an angle θ, this angle being equal to ϕ plus the angle of friction of earth against the back, AO, of the wall AOKL.

Take X so that EA × EB = (EX)².

Then AOX is the triangle of maximum pressure against the wall.

Draw AF (a) and GO (c) perpendicular to OB, then,

$$\text{Maximum thrust} = \tfrac{1}{2}w\,(c - \sqrt{c(c-a)})^2,$$

where w = weight of a cubic foot of earth.

Describe a semicircle on GO (figs. 153A and 153B). Draw AD parallel to OB, cutting the semicircle at D. With G as centre and OD as radius describe a circle cutting GO at P, and join DP, then,

$$\text{Maximum thrust} = \frac{w}{2}\,(\text{OP})^2, \text{ acting at } \tfrac{1}{3}\text{ AO, and making an angle } \theta \text{ with the normal to AO.}$$

Walls for Railway Cuttings.

For walls over 18 ft. in height—

Thickness at bottom = $\frac{2}{3}$ height − 3 ft.

For walls less than 18 ft. high—

Thickness at bottom = $\frac{1}{3}$ height + 3 ft.

The two equations give the same result for a height of 18 ft. No allowance is necessary for a surcharge of less than 6 ft. (*Pennsylvania Railroad Co.*)

Pressure of Water.

The moment of pressure of water on a retaining wall per each foot of length of wall is $d^3 \times 10{\cdot}4$, where d is the depth of water in feet. This is the moment at 1 foot. The total pressure is $31{\cdot}2\,d^2$, assumed to be concentrated at one-third the depth from the bottom of the water. Hence the moment $10{\cdot}4\,d^3$. The weight of the wall may be assumed concentrated at its centre of gravity, and the effect of the pressure of the water is to turn the wall upon the point O (fig. 153C). Calling H the height of the wall in feet, and t its thickness in inches, and assuming one cubic foot to weigh 120 pounds, the moment of stability is $\frac{\text{H}\,t^2}{2{\cdot}4}$ for rectangular walls, per foot of length; or $d^3 \times 10{\cdot}4$ must not exceed $\frac{\text{H}\,t^2}{2{\cdot}4}$; or $t^2 = \frac{25\,d^3}{\text{H}}$. This enables the thickness of a wall to be determined, that will exactly balance the pressure. Safety would be just secured by adding 50 per cent. to the thickness at the base, and subtracting the same amount from the top thickness, thus

giving the wall a sloping back as per dotted line, increasing the acting leverage of the C.G. (centre of gravity) of the section, so that the resultant pressure will now fall within the middle third of the wall thickness. This method is approximate and useful for small construction. Large masonry dams require more special consideration, and may be designed by calculations at each few feet of depth, designing the wall in a series of steps and drawing a final shape to enclose the whole in one harmonious section, which must also fulfil the conditions of strength proper to the material and crushing stress. Special care is necessary that water does not get in between bed joints, as it would greatly assist to turn a wall over.

It is usually considered desirable that the resultant of pressure on a wall should fall within the middle third of its thickness. Thus in fig. 153D, if $a\,b$ to any scale represents the total pressure $31{\cdot}2\,d^2$ concentrated at the centre of pressure upon the face of a wall, and $b\,c$ to the same scale is the weight of the wall, the line $b\,c$ being drawn through the C.G. of the cross section, then if the diagonal of the rectangle $a\,b\,c\,d$ cuts the base of the wall within its middle third of thickness, the wall may be assumed fully safe. If the diagonal fall outside the middle third, the thickness of the wall must be increased. It may be made safe by building the wall higher, and thus loading it; but the danger of this method is that a greater area is exposed to wind pressure, and if margins of safety are narrow the addition may be worse than useless in small work. Where a tank wall forms a continuation of an earth retaining wall, for example, special care is necessary.

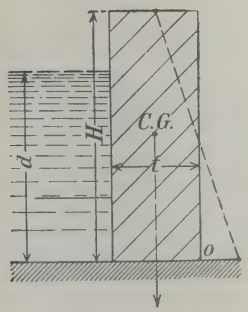

FIG. 153C.

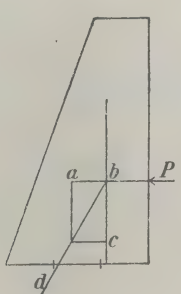

FIG. 153D.

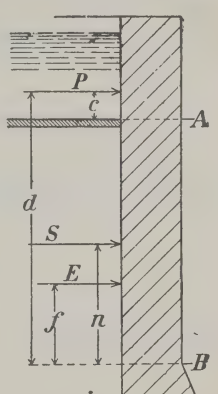

FIG. 153E.

The upper part of the wall must be safe at the bed joint level with the bottom of the tank and the wall, taken as a vertical cantilever subject to a lateral thrust at a distance two-thirds of the water depth from the water surface; it must be safe against overturning at any joint lower down. It must also be safe against the added thrust of the earth behind the lower portion plus the further pressure due to the tank full of water above, which must be treated as per the rule of page 510, fig. 155. Thus in fig. 153E the wall must be safe on the line A against the moment of the water pressure P c. It must be safe at the line B against the moment (P $\times$ d) + the moment (E $\times$ f) + the moment (S $\times$ n). Here E is the horizontal component of the earth pressure, and f is one-third A B; S is the horizontal component of the surcharged load, and n is one-half of A B. The safety must be proved at sufficient other depths between B and A and below B. Economy is promoted by sloping the wall against the earth between the points A and B. The wall in the figure is palpably erroneous, being far too thin for its height; it might be made safe by a sufficiency of cross-ties buried in the concrete bottom of the tank, in which case the wall from A to B must be made safe by treating it as a beam exposed to a virtual load at S and E.

Equilibrium of Retaining-Walls.

By Rankine's theory the pressure of earth on a vertical plane, AB (fig. 154), may be considered as acting at a point, P, one-third AB from base A, and in a direction parallel to the surface. Let w = weight of earth in pounds per cubic ft., ϕ = angle of repose of earth, P = total pressure, h = height of wall in feet.

For a bank with horizontal top.

$$P = \frac{wh^2}{2} \cdot \frac{1 - \sin\phi}{1 + \sin\phi}.$$

For bank with any surface slope, θ, of indefinite length

$$P = \frac{wh^2}{2} \cos\theta \frac{\cos\theta - \sqrt{\cos^2\theta - \cos^2\phi}}{\cos\theta + \sqrt{\cos^2\theta - \cos^2\phi}}.$$

For bank with maximum surface slope, ϕ, of indefinite length

$$P = \frac{wh^2}{2} \cos\phi.$$

For bank with surface slope of definite length an intermediate value is taken.

To resist the pressure there is weight of wall and of earth, ABD, resting on its back, which call W; this acts vertically from centre of gravity, G. The revetment may fail by overturning round f, by crushing at f, by sliding on Af.

Overturning round f.—On any scale make $oa = W$, $ob = P$; then oc is resultant (R), acting in direction oe at e. If e falls within base, the revetment will not overturn without crushing the toe at f; but e should fall within the centre third of Af.

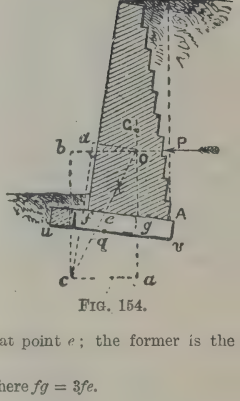

FIG. 154.

Crushing at f.—The resultant, R, must be resolved into two forces, cd (N), perpendicular to, and do parallel to, Af, acting at point e; the former is the crushing force.

Pressure per square inch at f on 1′ length of wall $= \frac{2N}{fg \times 12''}$, where $fg = 3fe$.

The pressure at f should not exceed power of material to resist crushing, divided by factor of safety, 4 to 8 (in practice seldom as high as 8).

Sliding on Af.—Force tending to produce sliding is od; force tending to resist it is N × co-efficient of friction at the joint Af. od should not exceed N × $\frac{4}{5}$ coefficient of friction.

Surcharged Wall.

If n = height of wall in feet, c = height of surcharge in feet, t = mean thickness of wall, in feet, to sustain horizontal bank; t' = mean thickness of wall, in feet, to sustain bank with indefinitely long natural slope, the factor of safety being about the same as for t; t'' = mean thickness in feet of surcharged wall; then

$$t'' = \frac{nt + 2ct'}{n + 2c}.$$

Effect of Weight of Buildings on Retaining-Walls.

Let w_1 = weight of building per unit of surface; the rest of the notation as at commencement. The total horizontal pressure, P, on revetment, due to the weight of building

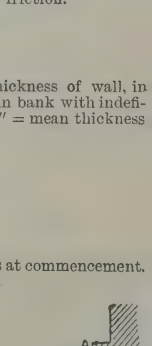
$$= w_1 (h - x) \frac{1 - \sin\phi}{1 + \sin\phi},$$

acting at $\frac{1}{2}$OB from O; and the total horizontal pressure, P_1, on revetment, caused by the earth

$$= \frac{w (h - x)^2}{2} \cdot \frac{1 - \sin\phi}{1 + \sin\phi},$$

acting at $\frac{1}{3}$OB from O.

If the front of the building were farther back from AO the effect would be less, but cannot be determined.



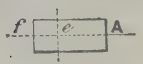


FIG. 155.

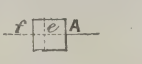
Foundations of Retaining-Walls.

Find the pressure perpendicular to uv (fig. 155), the weights and pressures being taken from point v instead of from A. If q is centre of pressure, qu should nearly equal qv, in order that the pressure may be uniformly distributed (this is unnecessary if the pressure at u is within what the earth can bear without yielding), and greatest pressure at u should not be greater than earth will bear, usually 1 to 1½ ton, or say 2,500 to 3,500 lbs. per square foot. Foundations to be carried deep enough to avoid effects of heat and frost.



Prof. Rankine advises that the distance, fe, of centre of pressure from outside edge in buttresses, chimneys, walls, &c., should be as follows :—In a

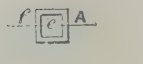
Rectangle (solid).

$fe = \text{or} > \frac{1}{3} fA.$

Square (solid).

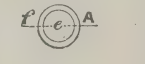
$fe = \text{or} > \frac{1}{3} fA.$

Ellipse (solid).



$fe = \text{or} > \frac{3}{8} fA.$

Circle (solid).



$fe = \text{or} > \frac{3}{8} fA.$

Hollow square (factory chimneys).

$fe = \text{or} > \frac{1}{6} fA.$

Circular ring (factory chimney).

$fe = \text{or} > \frac{1}{4} fA.$

Example of Brick Retaining-Wall.

Brickwork in mortar 100 lbs. per cubic ft., with a resistance to crushing of 500 lbs. per sq. in. and factor of safety of 8. Coefficient of friction for damp mortar, ·7. Weight of earth (w), 110 lbs. per cubic ft. ; angle of repose (ϕ), 37°. Pressure on foundation of sandy gravel not to exceed $1\frac{1}{2}$ ton per sq. ft. Height of wall (h) above footings, 18 ft. Wall sustains horizontal bank level with top. Top of wall two bricks thick, to allow of solid coping. Batter, $\frac{1}{12}$.

Assume for trial fA (fig. 154) = $\frac{1}{3}h$ = 6 ft. The back of wall being built with offsets of $4\frac{1}{2}$' at every 18" in height, DB will = 3'. Foundations to be 3 ft. below ground.

Weight of wall above bed joint, fA = 6,750 lbs. per foot run of wall.
„ earth in front of AB = 3,025 „ „ „
Total weight on fA = 9,775 lbs. = W „ „

The wall is more likely to overturn at f than at any other point ; it will be sufficient, therefore, to inquire into the stability of that joint.

$$P = \frac{wh^2}{2} \frac{1 - \sin\phi}{1 + \sin\phi} = 4{,}594 \text{ lbs.,}$$ which acts at P ; AP being one-third AB.

Drawing the parallelogram of forces, oc cuts Af at e, making $fe = 9\frac{1}{2}$".

Resolving oc perpendicular and parallel to Af gives cd = 10,100 lbs.

Pressure per sq. in. at $f = \frac{2 \times 10100}{3 \times 9\frac{1}{2}'' \times 12''} = 59$ lbs.

This gives a factor of safety of 10, which is more than sufficient.

Angle ocd will be found to be 20°, tan 20° = ·36, which gives a factor of safety of 2, the coefficient of friction being ·7. The wall is therefore stable.

The pressure on foundations perpendicular to uv will be found to be 14,000 lbs., or $6\frac{1}{4}$ tons, acting at q. To equalise the pressure on the earth, let $qu = qv$, which will make $uv = 12\frac{1}{2}$ ft., giving a pressure of about $\frac{1}{2}$ ton per sq. foot ; but as the earth will bear $1\frac{1}{4}$ ton without yielding, a much less width will suffice.

Practical Rules for Retaining-Walls.

A mean thickness of one-fourth height with counterslope of one-fifth, built in steps, will not be far wrong for light soils. This gives a bottom thickness of about one-third height, a centre thickness of one-fourth height, and a top thickness of one-seventh height. A mean thickness one-third height will generally do for stiff clay.

The following rule has been extensively used for brick retaining-walls :—

Top thickness, 1 ft. $10\frac{1}{2}$ in. ; face batter of 1 in 6, and after every five courses from top increase thickness by half a brick ; front batter should not be more than one-sixth, or it will let in moisture

and encourage vegetable growth in the joints. Long walls should have counterforts at back. Walls retaining soils through which water freely passes, such as clean gravel and sand, should have a French drain of loosely packed rubble, &c., running along the back footings, from which good-sized weepholes, from 6 to 10 ft. apart, should lead through the base. With more retentive soils a French drain at least 9 or 12 inches wide should run nearly the whole way up the back of the wall. In some cases extra weepholes at higher levels may be advisable. The mouths of the weepholes should always be carefully protected by loose packing.

Trautwine's Rule for Retaining-Walls.

The horizontal thickness (*ab*, fig. 156) at the base of a vertical or nearly vertical retaining-wall, *cdba*, which sustains a backing of either sand, gravel, or earth, level with its top, *cd*, as in the figure should not be less than the following in railroad practice, when the foundations are not more than about 3 feet deep.

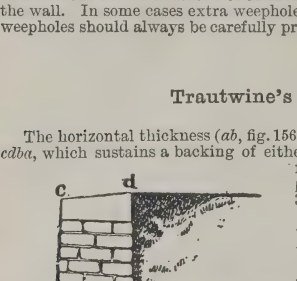


FIG. 156.

When the backing is deposited loosely, as usual, as when dumped from carts, cars, &c.—

Wall of cut stone or of first-class large-ranged rubble in mortar, *ab*. . . . ·35 of its entire vertical height, *db*.

Wall of good common scabbled mortar-rubble or brick . . . . . ·4 of its entire vertical height, *db*.

Wall of well-scabbled dry rubble . . . ·5 of its entire vertical height, *db*.

With good masonry, however, we may take the height *ds* instead of *db*, and then the above proportions of *ds* will give a sufficient thickness at the ground-line, *os*.

When the backing is somewhat consolidated in horizontal layers, each of these thicknesses may be reduced, but no rule can be given for this.

The offset, *oe*, in front of the wall is not included in these thicknesses.

When, however, the backing is a pure clean sand or gravel, we should use only the full dimensions, inasmuch as the tremor caused by passing trains would neutralise any supposed advantage from ramming materials so devoid of cohesion. Such sand may be rammed with much advantage for the purpose of compacting it in foundations; but a different principle is involved in that case. When it is done, even with cohesive earths, with a view of saving masonry in retaining-walls, it is probable that the expense will generally be found quite equal to that of the masonry saved.

The base, *ab*, in fig. 156, is four-tenths of the height, *bd*. In the foregoing thicknesses at base, the back, *db*, of the wall is supposed to be vertical; and the face, *ca*, either vertical or battered (sloped or inclined backward) to an extent not exceeding about 1½ inch to a foot; which limit it is rarely advisable to exceed in practice, owing to the bad effect of rain, &c., upon the mortar when the batter is great. The base of a vertical wall need not, in fact, be as thick as one with a battered face; but when the batter does not exceed 1·5 inch to a foot the difference is very small.

A mixture of sand or earth with a large proportion of round boulders, paving pebbles, &c., will weigh considerably more than the materials ordinarily used for backing, and will exert a greater pressure against the wall, the thickness of which should be increased, say, about one-eighth to one-sixth part, when such backing has to be used.

The wall will be stronger if all the courses of masonry be laid with an inclination inwards, as at *oeb*; especially if of dry masonry, or if time cannot be allowed (as it always should be when practicable) for the mortar to set properly before the backing is deposited behind it. In retaining-walls, as in the abutments of important arches, the engineer should place as little dependence as possible upon mortar, but should rely more upon the position of the joints for stability.

An objection to inclining the joints in dry (without mortar) walls is that rain-water, falling on the battered face is thereby carried inward to the earth backing, which thus becomes soft, and settles. This may be in a great measure obviated by laying the outer or face courses horizontal; or by using mortar for a depth of only about a foot from the face. The top of the wall should be protected by a coping, *cd*, which had better project a few inches in front. After the masonry has been built up to the surface of the ground, the foundation pit should be filled up; and it is well to consolidate the filling by ramming, especially in front of the wall.

The back, *db*, of the wall should be left rough. In brickwork it would be well to let every third or fourth course project an inch or two. This increases the friction of the earth against the back, and thus causes the resultant of the forces acting behind the wall to become more nearly vertical, and to fall farther within the base, giving increased stability. It also conduces to strength not to make each course of uniform height throughout the thickness of the wall, but to have some of the stones (especially near the back) sufficiently high to reach up through two or three courses. By this means the whole masonry becomes more effectually interlocked or bonded together as one mass, and therefore less liable to bulge. Very thick walls may consist of a facing of masonry and a backing of concrete.

Where deep freezing occurs the back of the wall should be sloped forwards for 3 or 4 feet below its top, as at *co*, fig. 157, which should be quite smooth, so as to lessen the hold of the frost and prevent displacement.

FIG. 157.

A slight bulging in a new wall does not necessarily prove it to be actually unsafe. It is generally due to the newness of the mortar and to the greater pressure exerted by the fresh backing, and will often cease to increase after a few months. It need not excite apprehension if it does not exceed ¼ inch for each foot in thickness at *a*.

After a wall, *abco*, fig. 158, with a vertical back has been proportioned by Trautwine's rule, it may be converted into one with an offsetted back, as *aino*. This will present greater resistance to overturning, and yet contain no more material. Thus, through the centre, *t*, of the back, draw any line, *in*; from *n* draw *ns* vertical; divide *is* into any even number of equal parts (in the figure

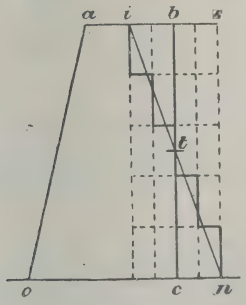

FIG. 158.

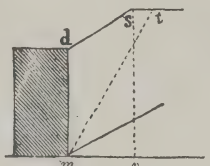

FIG. 159.

there are 4), and divide *sn* into one more equal part (in the figure there are 5). From the points of division draw horizontal and vertical lines for forming the offsets, as in the figure.

When, as in fig. 159, the backing is higher than the wall, and slopes away from its inner edge, *d*, at the natural slope, *ds*, of 1½ to 1, the following thicknesses at base will at least be found sufficient for vertical walls with sand. They are deduced from experiments.

In Table I., the first column contains the vertical height, *sv*, of the earth, as compared with the vertical height of the wall, which latter is assumed to be 1; so that the table begins with backing of the same height as the wall, as in fig. 156. Without increasing the base these vertical walls may be changed to others with battered faces to any extent not exceeding 1½ inch to a foot, or 1 in 8, without sensibly affecting their stability.

TABLE I.

Total Height of the Earth, compared with the Height of the Wall above Ground.	Wall of Cut Stone in Mortar.	Good Mortar Rubble or Brick.	Wall of Good Dry Rubble. When the earth reaches above the top of the wall, as in figs. 159 and 160, the wall is surcharged, and the earth that is above the top is called the surcharge. When the surcharge is carefully deposited above the wall, so as to slope back at a steeper angle than 1½ to 1, as, say, at 1 to 1, theory does not require the wall to be as thick.

WHARF WALLS

are an instance where the thickness should be increased, notwithstanding that the pressure of the water in front helps to sustain them. The earth behind such walls is not only liable to be very heavily loaded when vessels are discharging, but is apt to become saturated with water, especially below low-water level, and thus to exert a very great pressure against the walls. Moreover, the water gets under the wall, and by its upward pressure virtually reduces its weight, and consequently its stability. The same cause, of course, diminishes the friction of the wall upon its base. Such walls are, therefore, very liable to slide if the foundation is smooth and horizontal, and have done so even when the foundation had a considerable inclination backward.

If the back is stepped according to the rule on p. 513, the proportionate thickness at base will, of course, be increased. Face batter, 1½ inches to a foot, or one-eighth of the height. Back either vertical, or stepped according to Fig. 158. The strength is very nearly equal to that of a vertical wall with a base of ·4 its height. Experience has proved that such walls, when com-

posed of well-scabbled mortar rubble, are safe under all ordinary circumstances for earth level with the top.

A retaining-wall is usually in greater danger for a few months after its completion than after time has been allowed for the mortar to harden perfectly and for the backing to settle. When there are suspicions of the safety of a new wall, it would be well to place strong temporary shores against it, at about one-third to one-half of its height above ground. In some cases permanent buttresses of masonry may be built for the purpose. They should be well bonded into the wall.

The pressure of the earth backing will be much reduced if the first few feet of its height be made up in thin horizontal layers, to be consolidated by being used by the masons instead of scaffolding, as shown at *h*, Fig. 156. Frequently this can be done without inconvenience, and at very trifling cost.

CHIMNEYS.

Stability of Chimney Shafts.

The limit of stability to be observed for chimneys is that the wind must never bring tension on any joint. Where this limit is reached, the weight of the shaft on that joint will vary from *nil* at the windward edge to a maximum at the leeward edge, and the maximum intensity of pressure will = mean pressure × 2, the minimum distance of the centre of pressure from the leeward edge being as given with reference to retaining-walls.

To calculate the Stability of Shaft at any Joint.

w = weight of material, in pounds per cub. ft.—say, 100 lbs. for brickwork.
W = total weight of shaft, in pounds, above given joint.
p = wind-pressure, in pounds per sq. ft., generally taken at 50 to 55 lbs. against side of *square* shaft, and at 25 to 28 lbs. on sectional area through axis of *round* shaft, owing to its reduced action on a cylindrical surface.
h = height of shaft, in ft., above given joint.
h_1 = height in ft. of centre of area supposed to be acted on by the wind, above given joint.
d = outer side of square, or diameter of round shaft, in ft., above given joint.
A = area of masonry, in ft., at a given joint.
m = leverage of W, in ft., = $\frac{1}{2}d$ — minimum distance of centre of pressure from leeward edge = $\frac{1}{2}d$ for *round* and $\frac{1}{3}d$ for *square* shafts.

Then, at the limit of stability laid down, ph_1, hh_1, or moment of wind-pressure at given joint = Wm, or moment of stability.

And $\frac{2W}{A}$, or maximum intensity of pressure at leeward edge, must = or < safe intensity of resistance of material to crushing. Before failure by sliding could occur in any chimney it would be blown over.

If
d = average breadth of shaft, h = height, b = breadth of base (all in ft.), W = weight of chimney, in pounds, c = co-efficient of wind-pressure per sq. ft. (this co-efficient varies with the cross-section of the chimney, and for square chimney = 56, for octagon chimney = 35, for round chimney = 28), then $c\frac{dh^2}{b}$ = W.

Thus, a square chimney of average breadth of 8 ft., 10 ft. wide at base, and 100 ft. high, would require to weigh 56 × 8 × 100 × 10 = 448,000 lbs. to withstand any gale likely to be experienced. Brickwork weighs from 100 to 130 lbs. per cub. ft., hence such a chimney must average 13 inches thick to be safe. A round stack would weigh half as much, or have less base.

Dimensions of Chimneys, General Rules, and Formulæ.

Outside diameter at ground should not be less than $\frac{1}{10}$th the height, unless it is supported by some other structure.

Batter varies from 1 in 60 to 1 in 10; 1 in 24 is very common. Or the batter should be from $\frac{1}{16}$th to $\frac{1}{4}$ inch to foot on each side.

Thickness of brickwork: One brick (8 or 9 in.) for 25 ft. from the top, increasing $\frac{1}{2}$ brick (4 to 4½ in.) for each 25 ft. from the top downwards. If the inside diameter exceeds 5 ft., the top length should be 1½ brick, and if under 3 ft. it may be ½ brick for 10 ft.

Generally a much less height than 100 ft. cannot be recommended for boiler chimneys, as the lower grades of fuel cannot be burned, as they should be with a shorter chimney.

Tall Chimneys should always stand alone; if connected with the rest of the buildings, the increased settlement due to their weight on so small a foundation area causes rupture in the masonry. The distance from furnace to shaft should not exceed ⅔ height of shaft. They should be built and allowed to settle before the connecting flue is made.

Circular form is best; with the same quantity of material it covers a great area, is therefore more stable, and the effect of wind upon it is much less.

In any case the flue should be circular; it can hardly be too large, as it can always be reduced by dampers. It should be lined with a detached skin of firebrick for a certain distance up, increasing in proportion to the heat of the vapours carried off, and separated from the main shaft by an air-space.

Chimneys to receive Vapours of a very high temperature are built altogether of fire-bricks.

Caps tie head of chimney together, but projecting caps catch the wind, and cause oscillation. A dangerous chimney has been saved by removing the cap.

The *Scaffolding* used for building a chimney should be so arranged that it does not prevent the chimney from settling.

The *Intensity of Draught* required varies with the kind and condition of the fuel and the thickness of the fires. Wood requires the least, and fine coal or slack the most. To burn anthracite slack to advantage a draught of $1\frac{1}{2}$ inch of water is necessary, which can be obtained by a well-proportioned chimney 175 feet high.

Design of Tall Chimneys.

45 feet is an ordinary height to serve two steam boilers, but in some towns, as Manchester and Leeds, 90 ft. is the minimum allowed. They are sometimes proportioned for height according to the coal burnt per week of 56 hours, thus :—

4	tons	per week =	75 ft. high.	50	tons	per week =	150 ft. high.
13	,,	,, =	100 ,,	100	,,	,, =	180 ,,
26	,,	=	120 ,,	150	,,	,, =	200 ,,

Another rule is to make the height of the chimney three times length of boiler plus twice distance of furthest boiler to chimney; this allows 1 ft. of height for every foot the gases travel round the boiler, and 2 ft. of height for every foot of external flue.

A round chimney should not exceed twenty-five times its internal diameter in height.

Prussian Government Rules.—In April 1902 the Prussian Government issued regulations for the construction of chimney-stacks. Square stacks to be designed for a wind pressure of $25\frac{1}{2}$ lbs. per sq. ft., with the centre of pressure at the centre of gravity of diametral vertical plane. Octagonal stacks, 71 per cent. of the above pressure, and circular stacks, 67 per cent. (*Engineering Record.*)

Thickness of Brickwork.—Up to 150 ft. high or 5 ft. inside diameter the top length is generally one brick (9 ins.) thick; above that height or diameter the top length should be one brick and a half thick, and the thickness should be increased by a $4\frac{1}{2}$-in. set-off at every 20 ft. below the top. The outlet at top and the throat or internal diameter at each set-off should be of the calculated size to give the necessary area plus allowance for friction.

Batter.—If the diameter of the throat is kept uniform and a $4\frac{1}{2}$-in. set-off occurs at every 20 ft., the intermediate portions being of uniform thickness, a batter of 1 in 53·33 will be given, but the London County Council require a minimum batter of 1 in 48 = $2\frac{1}{2}$ ins. in 10 ft., and besides that it will be requisite in most cases to provide a firebrick lining for at least the bottom 15 ft. or 20 ft., having a thickness of $4\frac{1}{2}$ ins. and a clear space from the outer brickwork of $1\frac{1}{2}$ in. to 2 ins., necessitating a still greater batter.

Chimney-Cap.—The chimney-cap or cornice, by the London County Council rules, must not project more than the thickness of the brickwork upon which it rests. It may be of cast-iron casings bolted together and filled with brickwork; or of granite or other good weathering stone the separate blocks being cramped together with galvanised-iron cramps, or with an iron hoop sunk into the top and protected with cement; or of brickwork in cement.

Diameter at Base.—The London County Council require that the width of a shaft at the base if square on plan must be at least one-tenth, and if circular on plan, at least one-twelfth of the total height.

Firebrick Lining.—The firebrick lining must be entirely self-supporting and have a clear space behind, to allow for expansion and contraction independently of the main structure. It is therefore necessary to cover the top of the space by an over-sailing course of bricks built out from the inside of the main shaft, protecting the space, but allowing a clearance above the lining of $\frac{1}{8}$ in. for every 5 ft. of its height, to permit of its expansion when heated. The average height of this lining is one-fifth height of shaft + 10 ft. A common height is 20 ft. and thickness $4\frac{1}{2}$ ins.; when of greater height it is necessary to make the lower part 9 ins. thick. No air bricks should be inserted in the outer wall, as is sometimes done with the idea of cooling the air space, any such

openings being very detrimental to the draught. The only possible inlet for air to the chimney shaft should be through the fire-bars or over the surface of the incandescent fuel.

The smoke inspectors of the London County Council have lately recommended openings into the chimney-shafts near the bottom to reduce the smoke nuisance. The real effect is to dilute the smoke with air before it reaches the chimney-top so that it is not so black when expelled, but it does not reduce the actual amount of carbon emitted except so far as it tends to spoil the draught and so to reduce the fuel consumption and boiler efficiency.

Foundation.—It is important to note that a tall chimney should stand on an independent foundation in order that the settlement, or compression of the soil, may be uniform. When a chimney is built close alongside a boiler-house, or within the four walls of a warehouse, it is sometimes placed on an extension of the other foundations and bonded in with other work, but this invariably leads to unequal settlement and subsequent cracks in the brickwork.

(*Professor Henry Adams, M.Inst.C.E.*)

Effective Area of Chimney.

(1)

The effective area of a chimney for a given power varies inversely as the square root of the height. The actual area in practice should be greater, because of retardation of velocity due to friction against the walls. On the basis that this is equal to a layer of air 2 inches thick over the whole interior surface, and that a commercial horse-power requires the consumption on an average of 5 lbs. of coal per hour, we have the following formulæ:

$$E = \frac{0{\cdot}3\ HP}{\sqrt{h}} = A - 0{\cdot}6\sqrt{A} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad 1$$

$$HP = 3{\cdot}33E\sqrt{h} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad 2$$

$$S = 12\sqrt{E} + 4 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad 3$$

$$D = 13{\cdot}54\sqrt{E} + 4 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad 4$$

$$h = \left(\frac{0{\cdot}3\ HP}{E}\right)^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad 5$$

In which HP = horse-power; h = height of chimney, in feet; E = effective area, and A = actual area in square feet; S = side of square chimney, and D = diameter of round chimney, in inches.

(2)

If

A = least internal area of flue, in inches.
a = area of grate, in feet,
HP = horse-power of boiler.
h = height, in feet, of chimney from fire-grate.
P = pounds of coal consumed per hour.

$$A = \frac{112\ HP}{\sqrt{h}} = \frac{12F}{\sqrt{h}}$$ (*Tredgold.*)

F being in this case = 9·33 HP, or 9·33 lbs. per H.P. hour.

(3)

If

W = coal burnt in lbs. per hour; A = area in square feet at top; h = height in feet; C = cubic feet water evaporated per hour.

$$A = \frac{W}{14\sqrt{h}}, \text{ or } \frac{1{\cdot}5\ C.}{\sqrt{h}}. \quad W = 14A\sqrt{h}. \quad h = \left(\frac{W}{14A}\right)^2.$$

Area for single boiler = $\frac{1}{8}$ grate area.
Chimney under 150 ft., more than one boiler = $\frac{1}{10}$ " "
" over 150 ft. = $\frac{1}{12}$ " "

$$\text{Area in sq. ins.} = \frac{\text{lbs. coal per hour} \times 12}{\sqrt{\text{Height in feet}}} \qquad \textit{(Bourne.)}$$

$$\text{,, ,, ,,} = 1\tfrac{1}{2} \text{ sq. ins. per lb. coal per hour.} \qquad \textit{(Murray.)}$$

$$\text{,, ,, ,,} = \frac{\text{Area of fire grate}}{\sqrt{\text{Height} \times 1{\cdot}58}}. \qquad \textit{(Elswick.)}$$

The force of draught in chimney is the deficiency in weight of the column of rarefied air in the chimney compared with a similar column of the external air.

Ordinary velocity of chimney gases $= 2{\cdot}4\ \sqrt{H}$. *(Adams.)*

A common rule is to make the flue and area of the chimney top equal to from $\frac{1}{8}$ to $\frac{1}{10}$ the area of fire-grate, without taking into account the height of the chimney.

To find the draught of a given chimney in inches of water: *Divide 7·6 by the absolute temperature of the external air* ($\tau_a = t + 460$); *divide 7·9 by the absolute temperature of the gases in the chimney* ($\tau_c = t' + 460$); *subtract the latter from the former, and multiply the remainder by the height of the chimney in feet.* This rule, expressed in a formula, would be:

$$d = h\left(\frac{7{\cdot}6}{\tau_a} - \frac{7{\cdot}9}{\tau_c}\right).$$

***To find** the height of a chimney* to give a specific draught power, expressed in inches of water: *Proceed as above through the first two steps, then divide the given draught power by the remainder*; the result is the height in feet. Or, by formula:

$$h = \frac{d}{\left(\frac{7{\cdot}6}{\tau_a} - \frac{7{\cdot}9}{\tau_c}\right)}.$$

To find the maximum efficient draught for any given chimney, the heated column being 600° F. and the external air 62°: *Multiply the height above grate in feet by ·007, and the product is the draught power in inches of water.*

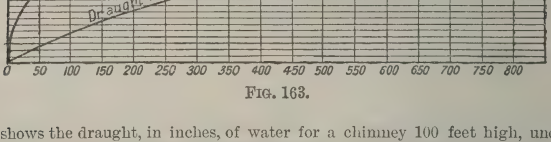

FIG. 163.

Fig. 163 shows the draught, in inches, of water for a chimney 100 feet high, under different temperatures from 50° to 800° above external atmosphere, which is assumed at 60°. The vertical scale is full size, and each division is one-twentieth of an inch. It also shows the relative quantity, in pounds of air, which would be delivered, in the same time, by a chimney under the same differences of temperature. It will be seen that practically nothing can be gained by carrying the temperature of the chimney more than 350° above the external air at 60°.

To determine the quantity of air, in pounds, a given chimney will deliver per hour, multiply the distance in inches, at given temperature, on the diagram, by 1,000 times the effective area in square feet, and by the square root of the height in feet. This gives a maximum. Friction in flues and furnace may reduce it greatly.

TEMPERATURE OF FLUES.

To find temperatures of flues, hang strips of metal foil on an iron wire across flues.

For pounds of coal burned per hour for any given size of chimney multiply the figures in the above table by 5. This is on the high side. If 1 lb. coal evaporates 8 lbs. water, then 5 × 8 = 40 lbs. of water evaporated per h.p., whereas in up-to-date condensing plants 20 and 15 lbs. water evaporated per h.p. may be taken as a good average. (*Horobin.*)

RATE OF COMBUSTION FOR DIFFERENT DRAUGHT PRESSURES.

(*W. S. Hutton.*)

Although the exact conditions are not specified for which the above table is calculated, the figures are approximately correct for stationary boilers burning medium sized anthracite coal. (*Horobin.*)

TOTAL DRAUGHT REQUIRED FOR EFFICIENT COMBUSTION OF DIFFERENT KINDS OF FUEL.

Fuel.	Total Draught, in Inches of Water.	Fuel.	Total Draught, in Inches of Water.
Straw	0·20	Slack, very small	0·7 to 1·1
Wood	0·30	Coal-dust	0·8 to 1·1
Sawdust	0·35	Semi-anthracite coal	0·9 to 1·2
Peat, light	0·40	Mixture of breeze and slack	1·0 to 1·3
Peat, heavy	0·50	Anthracite, round	1·2 to 1·4
Sawdust, mixed with small coal	0·60	Mixture of breeze and coal-dust	1·2 to 1·5
Steam coal, round	0·4 to 0·7	Anthracite slack	1·3 to 1·8
Slack, ordinary	0·6 to 0·9		

(*W. S. Hutton.*)

The above must be considered as applying only under ordinary conditions, and is only approximate. (*Horobin.*)

ARCHES.

Setting-out Arches.

Semi-elliptical Arch (fig. 164).—To set out a *semi-elliptical arch*, draw a line, AB, equal to the span or transverse axis of the ellipse. At the centre of AB draw the semi-conjugate, CD, at right angles, equal to the rise. Then, from the vertex, C, with radius AD or DB equal to half the span, describe an arc intersecting AB in E and F.

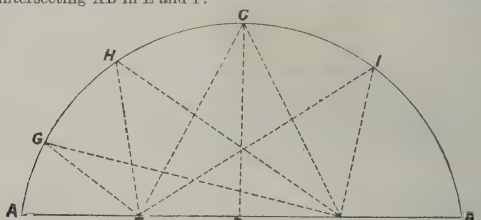

FIG. 164.

The points E, F, will be the foci of the ellipse. If two nails or pegs be fixed in the foci, and a line attached to them equal in length to AB, then the curve traced by a nail, keeping this line stretched, will be the ellipse required; the lines EGF, EHF, ECF, EIF, &c., being all equal to span AB, and to each other.

Many-centred Circular Arch.—Curves formed of arcs of circles of unequal radii, and similar in appearance to the ellipse, are sometimes adopted for the arches of bridges; with the same rise and span, they may be constructed to give a greater waterway, and in stone bridges they have been preferred by practical stonecutters, but in brick bridges they have no advantage in simplicity over elliptical arches. They may be described with three or a greater odd number of centres. The number of centres will depend on the relation between the span and rise; when the latter is one-third, or a greater fractional part of the former, three centres may be used, but if the rise is less than one-third of the span, then five, or a greater odd number, must be taken. In practice it will be found troublesome to describe arcs from a large number of centres, nor, indeed, will occasion be found for using curves of this description. The following is a method of describing a curve composed of three arcs each of 60°.

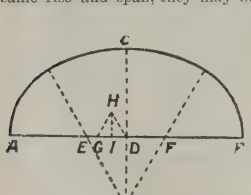

FIG. 165.

Let AB (fig. 165) represent the span, and CD the rise. Take DG = AD − DC, and on it describe an equilateral triangle, DGH; let fall the perpendicular HI, and take

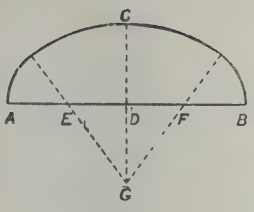

FIG. 166.

IE = HI. Lay off DF = DE. On EF describe the equilateral triangle EFK; then E, F, and K will be the centres required.

For an oval arch, rise one-third, bisect the half-spans AD and DB (fig. 166) in the points E and F, and produce versed sine CD to G, making DG = DC: then E, F, and G will be the three centres with which the curve may be described. In setting out arches, the practical difficulty arises from the elasticity of string. Instead of a string, soft wire about a tenth of an inch in diameter should be used. When the radius does not exceed 12 or 15 feet, a slip of wood may be used, with a nail at each end.

To find the Depth of Keystone for first-class Cut-stone Arches, whether Circular or Elliptic.

$$\text{Depth of key in feet} = \frac{\sqrt{\text{Rad.} + \text{half span}}}{4} + \cdot 2 \text{ foot.}$$

For second-class work this depth may be increased about one-eighth part; or for brick or fair rubble, about one-third.

TABLE.

Depths of Keystones for Arches

Of first-class cut stone. For second-class add about one-eighth part. For brick or fair rubble add about one-third part.

Span.	Rise, in Parts of the Span.						
	½	⅓	¼	⅛	⅛	⅛	1/10

300	4·53	4·62	4·80				

In large arches it is advisable to increase the depth of the archstones toward the springs; but when the span is as small as about 60 to 80 or 100 feet, this is not at all necessary if the stone is good, although the arch will be stronger if it is done. In practice this increase, even in the largest spans, does not exceed from ¼ to ½ the depth of the key, although theory would require much more in arches of great rise.

Amount of Pressure sustained by Archstones.

In bridges of the same width of roadway, if all the other parts bore to each other the same proportion as the spans, the total pressure would increase as the squares of the spans, while the pressure per square foot would increase as the spans. But in practice the depth of the archstones increases much less rapidly than the span; while the thickness of the roadway material, and the extraneous load per square foot, remain the same for all spans. Hence the total pressures, at key and at spring, increase less rapidly than the squares of the spans, but more rapidly than the simple spans; as do also the pressures per square foot. Thus, in two bridges of the same width, but with spans of 100 and 200 feet, with depths of archstones taken from the table on page 521, and uniform from key to spring, supposed to be filled up solid with masonry of 160 lbs. per cubic foot to a level of about 15 inches above the crown (including the stone paving of the roadway), with an extraneous load of 100 lbs. per square foot, the pressures will be approximately as follows:

Rise.	Span 100 Feet.				Span 200 Feet.			
	At Key.		At Spring.		At Key.		At Spring.	
	For 1 foot in width of its entire depth.	Per square foot.	For 1 foot in width of its entire depth.	Per square foot.	For 1 foot in width of its entire depth.	Per square foot.	For 1 foot in width of its entire depth.	Per square foot.
	Tons.	Tons.	Tons.	Tons.	Tons.	Tons.	Tons.	Tons.
$\frac{1}{6}$	42¼	13¾	58	18¾	126	29¼	179	42
$\frac{1}{5}$	36¾	12¼	57	19	112	27¼	181	44
$\frac{1}{4}$	31½	11	57½	20	97	24½	188	47½
$\frac{1}{3}$	25	9	61½	22½	80¼	21	207	54½
$\frac{1}{2}$	18	6¾	67½	25	57½	15½	230	61½

It will be seen that with the same span the pressure at the key becomes less, while that at the spring becomes greater, as the rise increases. Also, that when the archstones are of uniform depth, the pressure at either spring of a semicircular arch is about 4 times as great as at the key; whereas when the rise is but one-sixth of the span the pressure at spring averages but about one-third greater than at the key. These proportions vary somewhat in different spans.

The greater pressure per square foot at the springs may be reduced by increasing the depth of the archstones towards the springs. This, however, is not necessary in moderate spans, inasmuch as good stone will be safe even under this greater pressure.

Thickness of Arches.

Centre of pressure at every joint of arch and abutment should fall within centre third.

Thickness of arch at crown $= \sqrt{r \times B}$, where r is the longest radius of curvature at intrados; B, as deduced from practice, is as follows:—

	Feet.
Arch above ground standing solitary between abutments . . .	B = 0·12
Arch forming one of series of arches with piers between . . .	= 0·17
Underground archway in hard materials, such as rock or conglomerate	= 0·12
Underground archway in gravel or firm earth	= 0·27
Underground archway in wet clay or quicksand	= 0·48

Centering for Arches.

Centering is made of such stuff as is available. Fig. 170 shows what would be suitable for a 20 ft. arch of brick 2 ft. 3 ins. thick. The king post and struts might be of 2-in. stuff. The lagging is of 1½-in. plank, with centres 3 ft. apart; if 4 ft. to 5 ft. apart it should be of 2-in. plank. The struts are often placed at right angles to the arch, as shown in dotted lines.

In centering for *concrete arches* the lagging should be of narrow battens. 3 ins. to 4½ ins., laid close, the joints being run in with whiting and plaster of Paris. The following dimensions have been followed:—25 ft. 6 ins. span; centres were 2 ft. apart, of 9-in. × 1½-in. stuff; lagging

4½ ins. × 1½ in., a 9-in. × 3-in. plank cutting into four for lagging, into two for ribs. There were two lines of intermediate supports. For flat or prismoidal roof of concrete 2-in. or 3-in. sheeting was used, on centres of 3-in. stuff, 4 ft. to 6 ft. apart.

The centres rest by the ends of their chords upon wooden *striking* or *lowering wedges*, for striking or lowering the centre after the completion of the arch. These consist of pairs of wedge-shaped blocks, as W, W, fig. 171, of hard wood from 1 ft. to 2 ft. long, about half as wide, and a quarter or more as thick (sufficient to lower the centre from, say, 2 ins. to 6 ins. or more, according to span and other circumstances).

It is of the utmost importance, especially in large arches, that the *centres should be lowered very slowly*, otherwise the momentum acquired by so heavy a body as an arch descending suddenly, even but 2 ins. or 3 ins., might possibly affect its shape, or even its safety. For this reason the wedges should not have a taper steeper than about 1 in 6 or 8 for arches of less than about 50 ft. span, or than 1 in 8 or 10 for larger spans. Vertical lines at equal distances apart should be drawn on the long sides of the wedges, as a guide for lowering them all to the same extent at a time; and this should not exceed in all about half an inch a day in intervals of about an eighth of an inch for 50 ft. spans, or about ·1 to ·25 of an inch per day in all for spans over 100 ft. Slowness is especially to be recommended in *brick arches*, not only because their greater number of

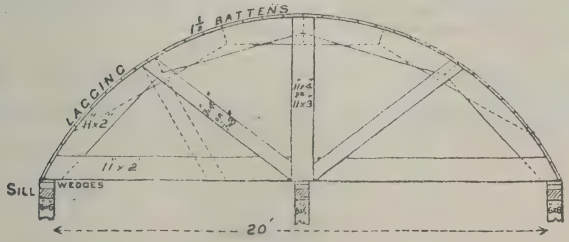

FIG. 170.

joints exposes them to greater derangement of shape, but because even good brick has much less than the average crushing-strength of good granite, limestone, or sandstone, and therefore is far more liable than they to crack, or even to crush, when the strains are thrown almost entirely upon their edges.

Easing and Striking Centres.—Much depends on temperature, mass of masonry or brickwork, composition of mortar, etc. With ordinary lime, centres should be eased while mortar is quite green, as soon as the arch is loaded to stability, and struck on an average after five to eight days. With small arches, one or two and a half bricks thick, 6 ft. to 8 ft. span, built in dry weather, the centres may be struck in three or four days. With slow-setting cement, if the arch be small and

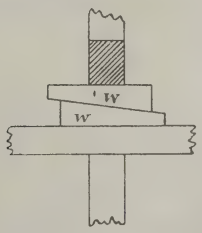

FIG. 171.

slight, so that it can be loaded to stability before the mortar of portion first commenced has set the centres may be eased, as with lime, but they may be struck sooner, and the limit may be taken as the time at which the joints would become too hard set to admit of being raked out for pointing without seriously injuring the brickwork. If, in consequence of the cement being strong and

quick-setting, or of the span or thickness of the arch being considerable, the arch cannot be completed before the portion first commenced has set, it is doubtful whether the centering should be eased at all, for fear of disturbing the setting of the cement. Centering for concrete should not be disturbed for at least fourteen days from the time of laying the concrete.

The main points to attend to are—to complete the arch to stability rapidly, and to prevent disturbance of the work while setting by traffic over it, or vibrations from adjoining work, otherwise the setting power, of cement specially, is destroyed.

PIERS.

Each should be calculated to resist the thrust when one of the arches it supports is covered with a travelling load, the other unloaded.

In a vertically-loaded arch ring, the thrust at the crown, and therefore the horizontal component of the thrust throughout the arch and against the piers, approximately = the total load per foot run × the radius of curvature of the centre line of the arch ring at the crown. The direction and amount of the resultant thrust against the piers are given by the load diagram corresponding to the line of resistance of minimum horizontal thrust, within the centre third of the arch ring.

Thickness of piers, generally from $\frac{1}{6}$ to $\frac{1}{8}$ span. Short piers have vertical sides; high piers may have side batter of $\frac{1}{12}$.

In viaducts and long bridges, 1 pier in every 5 or 6 may be thickened as an abutment pier, so that an accident to a part may not cause the destruction of the whole.

BRIDGES.

(Contributed by Reginald Ryves, M.Cons.E., Assoc.M.Inst.C.E.)

Superstructures.

The information given in the following tables respecting the strengths of various rolled sections is, as regards the larger scantlings, more particularly applicable to those cases in which simplicity in design is to be aimed at, in order, for instance, that erection and riveting-up may be easy, and the surfaces of the bridge parts convenient of access for painting. The tables give a sufficient number of values for the purposes of preliminary calculations of dead load, comparisons of the costs of girders or spans of different forms, and generally for approximate estimates. Since the lightest strut or joist is by no means always the most economical in the long run, the values for equal-sided angles as struts and for unequal-sided angles as beams, are given for considerable lengths. As regards struts the figures for light loadings on long diagonals are useful in calculating the strength of a tension member under the compression stress which might occur in the case of very unequal loading of the span, or during erection. In some cases, the two sets of values for channels as struts will show whether bracing is necessary.

An allowance for corrosion will, in some cases, be considered to be included in the factor of safety, but in the case of a bridge subjected to the effects of a corrosive atmosphere and those the painting of which is likely to be badly done, a definite allowance is sometimes made, and the thickness found necessary by calculation is increased in the actual design, the next thicker scantling being employed. For the calculation of tension in members, the cross-sectional area can quickly be found by dividing the weight per foot run of the scantling by the weight of a foot of 1-in. by 1-in. bar of the same material, for steel approximately 3·4 lbs. For tension members, a working stress of $7\frac{1}{2}$ tons per sq. in. is much used, somewhat higher values being sometimes employed in the case of very large spans. For some kinds of highway bridge girders a lower value is sometimes used, especially when there is no separate allowance for impact. For strut calculations the factor of safety is usually that involved in taking the actual load as a definite proportion of the crippling load. In this case the ultimate crushing strength of the material is a factor. Sometimes, however, the working load is calculated directly, and then some proportion of the ultimate strength of the material is employed. For some sections, especially for angles and tees, the formulæ in which the radius of gyration is used are more convenient than those in which the least dimension, or the overall dimension at right angles to a particular axis, is employed. (See formula for struts, p. 299.)

Strengths of Different Sections as Beams and as Struts.

Calculated by Fidler's formula for struts with fixed ends, assuming an ultimate strength of 60,000 lbs. per sq. in. and allowing a factor of safety of 5.

(Extracted from the Tables in Messrs. R. A. Skelton & Co.'s ' Structural Steel ' Handbook.)

Note on the Foregoing Tables.

The assumed ultimate strength of 60,000 lbs. per sq. in. is approximately 26·8 tons per sq. in. For an assumed ultimate strength of 70,000 lbs. per sq. in., or nearly 31·2 tons per sq. in., the values in the tables multiplied by $\frac{7}{6}$ would be approximately correct. Similarly, for a factor of safety of 4, multiply the values by $\frac{5}{4}$.

Waterway of Bridges.

The simplest cases of waterway calculation are those in which the conditions are such that the amount of heading up is not restricted. In these cases the limiting velocities which may be allowed decide the area of waterway which is necessary. Above the bridge the mean velocity of the stream will be reduced by the heading up.

It may be assumed that the water surface will fall to the original water level before it passes the piers, unless the channel of the river below the bridge has been altered. Taking the water level as the same, the new depth will be the same as the original depth, *plus* any lowering of the bed of the stream at the bridge site. The new width may be taken as the length of waterway. These two dimensions give the new area from which the new velocity can be calculated directly from the discharge or by

$$V_2 = V_1 \times \frac{d_1 l_1}{d_2 l_2}.$$

d_1 = original depth, d_2 = new depth.
l_1 = mean width of stream cross-section.
l_2 = length of waterway.

The new mean velocity is that to which the piers of the bridge are subjected, as well as the bed of the stream for a short distance below the bridge. This distance depends on the velocity and depth of the current. The limiting velocities can best be decided by a study of records of the behaviour of local strata and local masonry under similar conditions. The following figures provide a rough guide to the velocities usually allowed.

Limiting Velocities in Feet per Second.

On clay, 0·70 to 1·0; on sand which must not be disturbed (shallow foundations) 1·2 to 1·5; on firm, pebbly beds, 3·0 to 3·5; on stony or shingly beds, 4·0; on stratified rock, 6·0; on hard rock, 10·0.

For inferior brickwork, with better masonry in the cutwaters, and on the floor of the waterway at the feet of the cutwaters, about 5·0; better masonry, up to about 8 ft. per second. For ordinary pitching (floor) about 5·0. For very well-shaped bridge openings with thick piers allowing of easy curves, higher values may be allowed, and very high values may be permitted when the masonry is exceptionally strong, such as ashlar of hard stone with fine joints.

Waterway Calculations.

In selecting the formulæ given below, considerable use has been made of Col. H. D. Love's Manual on 'Hydraulics'; but the responsibility for the application of each formula and for the coefficients suggested rests with the author of the present article.

In the case of a bridge or culvert intended for the passage of flood waters which pool up on the upstream side, the discharge may usually be calculated without velocity of approach, especially when the water level on the downstream side is not much lower. This is an ordinary case where a railway embankment crosses land liable to flooding. The head is the difference between the water level below the opening and that above it, when the latter has reached its maximum. This may be a natural maximum, or one fixed by the discharge capacities of the bridges and culverts through the embankment. The amount of headway above this level, under the bridge floor, will depend upon what flotsam is carried by the water in floods.

The formula for discharge is:—

$$D = c\,A\,\sqrt{2gh}.$$

D = discharge in cubic feet per second (cusecs); A = area of opening in square feet up to the lower water level; h = head, or difference of water levels; g = 32·2 approx.; c is a coefficient depending partly upon the size of the opening, and partly upon its form, especially the curves of the cutwaters and wing walls. Ordinary values are in many cases 0·90; for large and well-designed openings, 0·92 to 0·95; for smaller openings, 0·85 to 0·90.

In the case of culverts through an embankment, or for bridges, for the maximum discharge before the embankment is overtopped, it may be necessary to know the discharge when the opening is drowned. If it is drowned on both sides the discharge is:—

$$D = c\,A\,\sqrt{2gh},$$

where h is the difference of water levels and c about 0·75 to 0·85, according to the form and size of the opening. Where the floor of the bridge presents a sharp edge a fairly low value should be taken and a fairly high value for well-shaped culverts.

When the upstream end is drowned and the downstream end is not drowned, the discharge is found by :—

$$D = c\,l\,\sqrt{2g}\left[\frac{2}{3}\left(h^{\frac{3}{2}} - h_2^{\frac{3}{2}}\right) + \left(h_1 - h\right)^{\frac{1}{2}}\right].$$

Where l = the width of the opening ; h = the difference in water levels ; h_1 = the head above the bottom of the opening ; h_2 = the head above the top of the opening ; c may be taken as 0·75 to 0·85. When the span is a long one and the waterway deep, a fairly high value may be given, but for a culvert the value may be taken as lower than that for the same culvert when wholly drowned.

In a considerable number of cases the waterway of the bridge is nearly as great as that of the stream, or quite as great when a single span clears the flood channel. Even with a considerable number of spans the bridge may obstruct the waterway very little if the piers are thin and are provided with good cutwaters and joinwaters. The velocity of approach may then be taken as v, the mean velocity of the stream, and the following relation will serve for preliminary calculations :

$$D = c\,A\,\sqrt{2g\,(h + h_a)}.$$

$h_a = \frac{v^2}{2g}$. $A = dl$ where l is the waterway of the bridge, and d the depth to the floor under the bridge. For sluggish streams h may be neglected, and for a stream with a sharp fall it may be taken as the fall in a length measured about $\frac{2}{3}$ that of the piers. This equation, so used, may be useful in preliminary calculations ; where, for instance, the mean velocity of the stream is measured, but not its cross-sectional area, or where the discharge has been separately found. In the case of a sluggish stream it may be possible to fix the value of d, approximately.

Calculations involving Afflux.

Where the actual fall is small, as in most large rivers, and where the bridge considerably impedes the river, the total head driving the water through the opening is usually calculated as : $(x + h_a)$, where x = the afflux and h_a = head equivalent to the velocity of approach. The discharge is then :

$$D = c\,A\,\sqrt{2g\,(x + h_a)}.$$

A = the smallest cross-sectional area of the waterway under the bridge, usually taken as that given by a water surface at the original water level :

$$x = \frac{v^2}{2g}\left(\frac{l^2}{c^2 {l_1}^2} - \frac{d^2}{(d + x)^2}\right).$$

l = the mean width of the stream ; d = mean depth of the stream below the bridge ; l_1 = the total width of waterway in the bridge openings ; c = coefficient of contraction, say 0·9 to 0·95 for large bridge openings and about 0·85 for small openings with only moderately good cutwaters and wing walls.

First insert the following provisional value of x in the right-hand side of the above equation.

$$x\ (\text{provisional}) = \frac{v^2}{2g}\left(\frac{1{\cdot}1\,l^2}{{l_1}^2} - 1\right).$$

This gives a new value of x.

Repeat the solution of the longer equation with the new value of x on the right-hand side.

Next, to find h_a.

The head is calculated as that at one place, due to afflux and velocity of approach, and the velocity of approach is, therefore, the new reduced velocity of the deepened stream above the bridges, thus :

$$v_a = \frac{d}{d + x}\,v, \text{ and } h_a = \frac{{v_a}^2}{2g}.$$

We can then use the equation :

$$D = c\,A\,\sqrt{2\,g\,(x + h_a)}.$$

If the length of the waterway is only estimated at first, within limits, take a probable value and having found x, find l_1 by the equation :

$$l_1 = \frac{vl\,(d + x)}{c\,\sqrt{[2gx\,(d + x)^2 + v^2 d^2]}}.$$

In some cases x will be decided by the maximum water level which may be allowed, and the value so found will be used in the equations.

Discharge through Long Culverts.

The foregoing formulæ for discharge are suitable for short culverts, and for fairly long culverts when the velocities are low. For long culverts and for high velocities the head necessary to carry the water through the barrel regarded as a pipe must be added. The heads may be found by a pipe discharge formula, or, for small diameter culverts, may be taken from the tables (see

'Waterworks'). As it is often very economical to pass water through culverts at fairly high velocities, the point is of some importance.

Loads on Bridge Foundations.

CYLINDER BRIDGE PIERS. APPROXIMATE SAFE LOADS PER SQUARE FOOT (*J. Newman*).

	Tons per Sq. Ft.
Firm sand in estuaries and bays	5·0 to 5·6
Considered safe on firm sand (in Holland)	6·0
Very firm, compact sand, foundations at depths not less than 20 ft.	6·7 to 7·8
Firm shale and clean gravel	6·7 to 8·9
Compact gravel	7·8 to 10·0

Calculated loadings (neglecting friction), tons per square foot: Benares bridge, 11·19; Jubilee bridge, 9; Gorai bridge, 8·5 (all deep foundations); Blackfriars bridge, 4·75; Rupnarayan bridge, 6·7 (or, assuming skin friction as 5 cwts. per square foot, the loading on the base of the pier is about 4·5 tons per square foot).

CLYDE BRIDGE, CALEDONIAN RAILWAY.

Caissons 48 to 89 ft. long and 20 to 23 ft. wide:

Land Piers.—Distances from river-bed about 50 and 60 ft.; depths below level of river-bed about 20 and 30 ft. Depths below quay level and loadings, 50 ft., 4·12 tons per sq. ft.; 61 ft., 4·73 tons; 57 ft., 4·75 tons.

River Piers.—Depths below river bed and loadings: 44 ft., 5·66 tons per sq. ft.; 44 ft., 5·96 tons; 48 ft., 6·04 tons; 44 ft., 6·12 tons.

SKIN FRICTION ON BRIDGE FOUNDATIONS.
(Caissons and 'Wells' or 'Cylinders.')
Foundations of the Empress Bridge over the Sutlej.

Brick Cylinders, 19 Ft. in diameter, sunk on an average 110 Ft.	Skin Friction. Cwts. per Sq. Ft.		
	Mean.	Max.	Min.
Average of 36 cylinders sunk to depths varying from 10 to 27 ft., average 19 ft., under their own weight only, 25½ to 33 tons, average 31 tons.	0·85	1·33	0·63
Average of 100 observations in sinking 36 cylinders, at depths from 17 to 64 ft., loads 31 to 249 tons, average 132 tons besides the weight of the cylinders.	2·13	4·08	1·29
Average of 9 observations in sinking 3 cylinders by pneumatic process at depths varying from 44 ft. to 63 ft.	2·71	3·52	2·32

Papaghni Bridge.—Cast-iron cylinders 12 ft. in diameter and brick cylinders of the same diameter. The following frictional resistances were noted when sinking the piers; cwts. per sq. ft. In the upper sand 2·08 to 2·20; in black clay, 3·50 to 5·60; in silt below the clay, 2·72 to 4·28; in the lower sand, 2·58 to 3·16.

Chittravati Bridge.—Friction through 33 ft. of sand, 10 ft. of clay, and 7 ft. of clay, sand, and boulders—2·32 to 3·77 cwts. per sq. ft. Friction through 33 ft. of sand, 10 ft. of clay, and 3 ft. of sand and clay—2·93 to 3·62 cwts. per sq. ft.

Tavy and Laira Bridges, Devonshire.—2·0 to 2·8 cwts. in mud.

Concrete Cylinders at Haulbowline Dockyard (H. E. Oakley).—Twenty-three cylinders, 8 ft. in diameter, were sunk through silt. The average skin friction for a cylinder varied from 4·2 to 8·6, the mean being 5·9. In only three cases was the average for a cylinder less than 5·2 cwt. per sq. ft. In seven cases the maximum resistance recorded exceeded 9 cwts. per sq. ft.

Caissons of Barnes Railway Bridge.—The caissons are 28 ft. by 18 ft. The skin friction in London clay was 2·03 cwts. for one, and 2·95 cwts. for the other, per sq. ft.

A Shaft sunk at Oxford Circus, London.—Skin friction only 1·0 cwt. per sq. ft. The low value being attributed to (1) the cylinder keeping its shape very well; (2) being kept very upright; and (3) a pocket being formed below the cutting edge and pugged clay inserted.

A Shaft sunk at Greenwich.—In sand and ballast, skin friction 4 to 4½ cwts.; in shelly clay, 6 cwts. per sq. ft.

UNIT LOADS ON BRIDGE MATERIALS.

Clyde Bridge, Caledonian Railway (D. A. Matheson).—Loads adopted as standards, tons per sq. ft.: concrete in foundations, 7; concrete in walls, 8; red brickwork in cement, 10; blue brickwork in cement, 15; freestone square rubble masonry in cement, 8; freestone ashlar masonry in cement, 15; granite ashlar masonry in cement, 25; freestone ashlar bearing blocks, 12; granolithic bearing blocks, 12; granite ashlar bearing blocks, 20.

Impact.

There is no general agreement among engineers as regards allowances for impact. Such allowances depend upon the span in relation to the size of the loads producing the effects considered under the head of impact; for instance, the length of the span in relation to a train or to a tramcar. They also depend upon the proportion of live load (impact load) to dead load. Another factor is speed. A traction engine may not demand so great an allowance as a motor van. No attempt will be made here to give general rules, but the following formula indicates one method :—

$$I = c\left(\frac{l}{l+d}\right) \quad \text{(Schaub)}$$

Where l=live load ; d=dead load ; c=a coefficient : about 0·75 for train loads, 0·30 for a rolling load of 20 tons on a highway bridge, 0·15 for a crowd load of 100 lbs. per sq. ft. ; I=impact allowance expressed as a proportion of the live load—to be added.

(See also under ' Railways,' page 550.)

Some of the formulæ used may be applied separately to the cross girders and decking.

For highway bridges, allowances such as 20 per cent. to 40 per cent. of the load causing impact effects are sometimes allowed to meet modern traffic conditions; some allowance should be made in the case of a girder span, and small allowances for other spans when the dead load is not very great compared with the live load.

Life of Timber Bridges.

Life of neglected Timber Bridges in New South Wales : Renewed between 1896 and 1902 (*H. H. Dare*).

Truss Bridges.—Life not exceeding 20 years, 7 (19 per cent.) ; 20 to 25 years, 13 (36 per cent.) ; 25 to 30 years, 6 (17 per cent.) ; exceeding 30 years, 10 (28 per cent.).

Beam Bridges.—Life not exceeding 20 years, 24 (25 per cent.) ; 20 to 25 years, 31 (33 per cent.) ; 25 to 30 years, 11 (12 per cent.) ; exceeding 30 years, 28 (30 per cent.).

Life of Timber Bridges, United States.—' All over the eastern part of the U.S.A. there are to be found timber truss bridges of the Burr & Howe types, which are even now safely carrying traffic after 50, 60 and even 100 years of constant use.' (Editorial in *Engineering News.*)

RAILWAYS.

RAILS.

There are two descriptions of rails in general use—viz. the ' Bull-headed Rail,' and the ' Flat Bottomed ' or ' Flanged Rail.'

Steel rails have superseded those of iron.

Dimensions of Rails Used on British Railways.

The standard rails of leading English railways are as follows: (1) Midland Railway, 100 lbs. per yard, 45 ft. long; (2) Great Western Railway, 97½ lbs., 30 ft.; (3) Great Northern Railway, 96 lbs.; (4) Great Central Railway, 96 lbs., 36 ft., and 86 lbs., 30 ft. long; (5) London and North Western Railway, 95 lbs., 60 ft.; (6) North Eastern Railway, 90 lbs., 30 ft.; (7) London and South Western Railway, 90 lbs.; (8) Lancashire and Yorkshire Railway, 86 lbs.; (9) Great Eastern Railway, 85 lbs. All of these are of the bull-head section, supported in heavy cast-iron chairs, to which they are secured by wooden wedges (or sometimes wedges of coiled steel). The chairs are fastened to the ties by round spikes and wooden spikes or trenails, through bolts being occasionally used.

BRITISH STANDARD SPECIFICATION AND SECTIONS OF BULL-HEAD RAILWAY RAILS.*

(No. 9—1909.) (*Abstract.*)

1. The steel for the rails shall be of the best quality made by the Bessemer, Siemens-Martin, or other process, to be approved by the engineer (or by the purchaser).

The rails shall show on analysis that in chemical composition they conform to the following limits:—

Carbon . from . .	0·35 to 0·5 per cent.	Phosphorus not to exceed .	0·075 per cent.
Manganese „ . .	0·7 to 1·0 „	Sulphur „ „ .	0·08 „
Silicon . not to exceed	0·1 „		

3. Each rail shall be made from an ingot not less than 12 ins. square at the smaller and 14 ins square at the larger end, and must be cogged down into blooms, and sufficient crop then sheared from each end to ensure soundness.

4. A rolling margin of ½ per cent. under to ½ per cent. above the calculated weight will be permitted, but the calculated weight only will be paid for.

* By permission of the British Engineering Standards Association

5. Table of General Dimensions of 'B.S.' Bull-Head Rails.

No of 'B.S.' Section.	Height of Rail.	Width of Head.	Calculated Weight of Rail.	No. of 'B.S.' Section.	Height of Rail.	Width of Head.	Calculated Weight of Rail.
Lbs. per yd. (nominal).	Ins.	Ins.	Lbs. per yd.	Lbs. per yd. (nominal).	Ins.	Ins.	Lbs. per yd.
60	$4\frac{3}{4}$	$2\frac{5}{16}$	59·79	85	$5\frac{1}{16}$	$2\frac{1}{16}$	84·88
65	$4\frac{7}{8}$	$2\frac{3}{8}$	64·58	90	$5\frac{3}{16}$	$2\frac{1}{8}$	89·77
70	5	$2\frac{7}{16}$	70·13	95	$5\frac{5}{16}$	$2\frac{1}{8}$	94·59
75	$5\frac{1}{8}$	$2\frac{1}{2}$	74·36	100	$5\frac{7}{16}$	$2\frac{1}{4}$	99·84
80	$5\frac{3}{8}$	$2\frac{9}{16}$	79·49				

8. The whole of the rails shall be of uniform section throughout, true to templates, perfectly sound and straight, and free from splits, cracks, burrs, and defects of every kind.

9. A quantity of short lengths will be taken in such lengths and quantities as may be ordered by the engineer (or by the purchaser), provided that these short lengths are cut down from longer lengths found to be defective at the ends only, and that the total quantity taken does not exceed $7\frac{1}{2}$ per cent. of the contract.

N.B.—The Committee recommend the adoption of the following as the normal lengths of rails, viz. 30 ft., 36 ft., 45 ft., or 60 ft.

10. The rails shall be the specified length at a temperature of 60°F. No rail will be accepted which is more than three-sixteenths of an inch above or below the length specified, whether for straight or curved line.

13. The brand shall be rolled on the web of the rail to show that the rail is of British Standard Section and made under the conditions of this specification.

14. From each cast one rail shall be selected by the representative of the engineer (or of the purchaser). From this a piece 5 ft. long shall be cut which shall be placed in a horizontal position with the bull head uppermost upon two iron or steel supports resting on a solid foundation, and placed so that their centres are 3 ft. 6 ins. apart, the upper surfaces of the supports being curved to a radius of 3 ins. The test shall comprise two blows delivered midway between the bearings from a falling iron weight of 2,240 lbs., the striking face of which shall be rounded to a radius of not more than 5 ins. The height of drop for the various sections of rails shall be as tabulated below. The blows must be sustained without fracture and the rail must show a deflection between the limits given below.

Tests of British Standard Bull-Head Rails.

No. of 'B.S.' Section and Nominal Weight of Rails per Yard.	Falling Weight Test.					
	1st Blow.			2nd Blow.		
	Drop	Deflection.		Drop	Deflection.	
		From	To		From	To
Lbs.	Ft.	In.	Ins.	Ft.	Ins.	Ins.
60	5	1	$1\frac{5}{16}$	10	3	$3\frac{3}{4}$
65	5	1	$1\frac{1}{2}$	12	3	$3\frac{3}{4}$
70	6	1	$1\frac{5}{16}$	12	3	$3\frac{3}{4}$
75	6	1	$1\frac{5}{16}$	12	3	$3\frac{3}{4}$
80	6	$\frac{7}{8}$	$1\frac{3}{16}$	15	3	4
85	6	$\frac{7}{8}$	$1\frac{3}{16}$	15	3	4
90	7	$\frac{7}{8}$	$1\frac{1}{4}$	20	3	$4\frac{1}{4}$
95	7	$\frac{7}{8}$	$1\frac{3}{16}$	20	3	$4\frac{1}{4}$
100	7	$\frac{7}{8}$	$1\frac{3}{16}$	20	3	$4\frac{1}{4}$

Should the length cut from the selected rail fail to comply with the test specified for its weight, two other rails from the same cast will be selected and similar lengths cut and tested, and the acceptance or rejection of the cast will be decided by the result of the three tests, so that if two of the rails selected fail to comply with the test the entire cast will be rejected.

15. From each 100 tons of rails the manufacturer shall (if required by the representative of the engineer or of the purchaser) cut a test piece from any rail selected as a sample rail; such test piece to be stamped to correspond with the sample rail. It shall then be placed in a testing machine of approved pattern, and shall show an ultimate tensile strength equivalent to not less than 40 tons per square inch, nor more than 48 tons per square inch, with an elongation of not less than 15 per cent. upon the Standard Test Pieces.

16. The holes for fishbolts must be drilled through the web from the solid at each end of the rails, of the sizes and in the position shown on the drawing attached to the specification or to a drawing to be supplied by the engineer (or the purchaser). These holes must be clean and square with the web, without burrs on either side, and will be checked with the gauges to be furnished to the manufacturer by the engineer (or by the purchaser). Should any of the holes vary from the correct size or position more than one-thirty second of an inch the rails in question will be liable to rejection.

FLAT-BOTTOMED OR FLANGED RAILS.

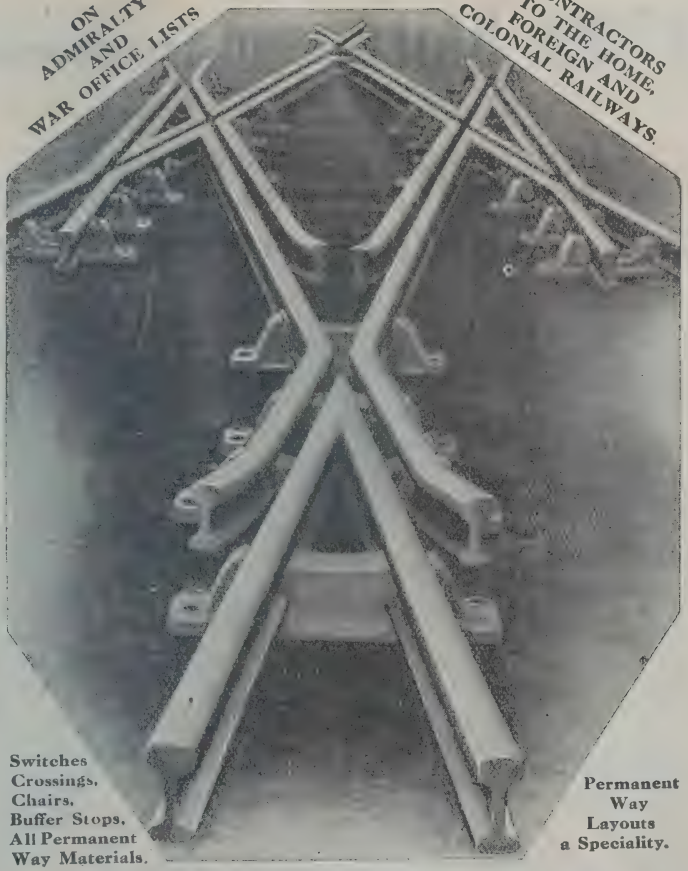
This form of rail is largely used in India, in the Colonies, and in America.

BRITISH STANDARD SPECIFICATION AND SECTIONS OF FLAT-BOTTOM RAILWAY RAILS.*

(No. 11—1909.) (*Abstract.*)

The general tests are the same as those for bull-head rails.

TABLE OF GENERAL DIMENSIONS OF 'B. S.' FLAT-BOTTOM RAILS.



No. of 'B.S.' Section.	Height of Rail.	Width of Head.	Nominal Weight of Rail.
	Ins.	Ins.	Lbs. per Yard.
20	$2\frac{1}{2}$	$1\frac{3}{8}$	20
25	$2\frac{3}{4}$	$1\frac{1}{2}$	25
30	3	$1\frac{5}{8}$	30
35	$3\frac{1}{4}$	$1\frac{3}{4}$	35
40	$3\frac{1}{2}$	$1\frac{7}{8}$	40
45	$3\frac{3}{4}$	$1\frac{21}{32}$	45
50	$3\frac{15}{16}$	$2\frac{1}{16}$	50
55	$4\frac{1}{8}$	$2\frac{13}{32}$	55
60	$4\frac{5}{16}$	$2\frac{1}{4}$	60

A Standard Specification for Light Flat-Bottom Railway Rails (10 to 20 lbs. per yard) and Fish Plates, is given in Report No. 104—1919.

Specification for Bolts, Nuts, Screws, and Spikes.

(LONDON AND NORTH WESTERN RAILWAY.)

Specification for Steel Bolts and Nuts.

The steel from which the bolts and nuts are made is to have a tensile strength of not less than 36 tons per square inch, with an ultimate extension of not less than 20 per cent. upon 10-inch lengths. The heads are to be worked out of the solid, and not welded on, and are to be stamped with the letter 'S,' as approved by the engineer. The heads and nuts are to be at right angles with the centre line of the bolts, and central with the shank, which must be perfectly straight. They must be screwed to Whitworth's standard, and the threads must be clean and smooth.

Specification for Galvanised Steel Screws for Rail Chairs.

The steel from which the screws are made is to have a tensile strength of not less than 36 tons per square inch, with an ultimate extension of not less than 20 per cent. upon 10-inch lengths. The heads are to be worked out of the solid, and not welded on, and are to be at right angles with the centre line of the screws, and central with the shank, which must be perfectly straight. Each screw is to have a deposit of zinc of not less than 180 grs. smoothly and uniformly distributed all over.

Specification for Steel Spikes.

The steel from which the spikes are made is to have a tensile strength of not less than 36 tons per square inch, with an ultimate extension of not less than 20 per cent. upon 10-inch lengths. The heads are to be worked out of the solid, and not welded on, and are to be at right angles with the centre line of the spikes and central with the shank, which must be perfectly straight. The heads are to be stamped with the letter 'S,' as approved by the engineer.

Sleepers.

These are usually made of Baltic red timber, and measure 9 ft. long, 10 ins. wide, and 5 ins. deep; at the joints the width is 12 ins. Each load of 50 cubic feet should be impregnated with from 40 to 50 gallons of creosote, equal to from 2½ to 3 gallons per sleeper.

Plugged sleepers have been used with marked success in large numbers by Chief Engineer Fredericia, of the Danish State Railway. A plain 1½-in. cylindrical creosoted plug of beech or birch is driven tight in a 1½-in. hole bored in the sleeper, and the spike is driven in a hole bored in this plug. Worn-out sleepers plugged in this way have been found to give good service, as the rail seems to be held down with exceptional firmness and deterioration due to the pounding of loose rails is prevented.

No. of 15-ft. rails per mile . . . 704			No. of 18-ft. rails per mile . . . 587		
„ 16-ft. „ „ . . . 660			„ 20-ft. „ „ . . . 528		

Weight of rail per yard in lbs. multiplied by 1/9 equals tons per mile of single track.
Approximately, the weight of a rail in kilograms per metre × 2 = weight in lbs. per yard.

Loss of Strength in Steel Rails through Use on Railways.

(*Abstract from Board of Trade Report* 1900.)

The Report of the Board of Trade Committee appointed to inquire into the loss of strength in steel rails through use on railways, states that :

(*a*) The preponderance of fractures near the ends of rails seems to show that the greater straining action due to discontinuity at the joint is a contributing cause of fracture, and this can be remedied by adopting rails of sufficient strength with webs of ample thickness and secure types of fastening, and by care that no looseness arises in service.

(*b*) The fact that worn rails are improved in strength and ductility by annealing proves that part of the deterioration of rails in service is of the nature of what is sometimes termed 'fatigue.'

(*c*) It appears certain that in some cases fractures of rails have been due to fissures formed during service. How far the minute transverse fissures, very often noticed in the running surface of old rails, give rise to these larger induced flaws requires further investigation. It is not likely that they usually spread into the substance of the rail, because they are common in old rails, and fractures would be more frequent than they are if that were the case. Also, the evidence as to the existence of visible flaws or defects in the fractured surface of rails is very conflicting. In some cases, undoubtedly, the combined effects of the weakening of a rail by wear and corrosion, possibly also increased straining action from defective packing of sleepers, and the presence of a flaw or fissure of not inconsiderable size have led to fracture of the rail. That such defects appear most commonly in the head of the rail is evidence to a certain extent that they are induced by the hammer hardening of the top surface.

(*d*) It is very desirable that the mechanical tests to which rails are subjected should be as far as possible standardised in connection with (1) the weight ; (2) the section ; and (3) the chemical composition of the rail.

As regards chemical composition the Committee does not think it desirable to insist upon too high a proportion of carbon, manganese, or silicon in the steel, having regard to the ordinary contingencies of manufacture, and the greater susceptibility of high carbon steel to thermal influences.

Mr. E. Windsor Richards (in conjunction with Mr. E. P. Martin, of Dowlais) considers, after careful consideration from the points of view of a manufacturer and user, that, exclusive of the iron, a steel rail should have the following range of composition :

	Minimum.		Maximum.
Carbon	·35	to	·5
Silicon	·05	„	·1
Sulphur	·04		·08
Phosphorus	—		·08
Manganese	·75	„	1·00

The falling weight tests showed conclusively that double-headed rails worn in service on one head and afterwards turned down to rest on the chair so as to bring the unworn head into use, are dangerously brittle, owing to the worn head having developed numerous incipient small cracks, which really form 'nicks;' and such practice of using rails is recommended to be immediately discontinued.

THERMAL INFLUENCES.

Seasons at which Fractures most frequently occur.—Mr. Footner has given the following data from twelve years' experience on the London and North Western Railway : Fractures in spring, 29 per cent. ; in summer, 16 per cent. ; in autumn, 22 per cent. ; in winter, 33 per cent. There is other evidence as to the frequency of fractures in winter, and no doubt when the permanent way is hardened by frost the effect of concussions on the rails is much more serious. There is no satisfactory evidence that the steel itself is sensibly weakened by any ordinary cold temperature.

According to all statistics more than 50 per cent. of fractures occur before the rails have had a service of fifteen years.

Mr. Footner states that of fractured rails

3 per cent. broke after ½ to 5 million tons. | 45 per cent. broke after 50 to 100 million tons.
35 „ carrying 5 to 50 tons. | 17 „ carrying 100 to 200 tons.

So that 38 per cent. of the broken rails had carried less than 50 million tons.

According to Dormus, if f = breaking stress of rail steel in tons per square inch; l = gauge length in inches; Δ = ultimate elongation of length l in inches; then $100f^2\Delta \div l$ should not be less than 22,000; only the worst qualities give a lower value than 16,120.

Sir I. Lowthian Bell does not think that the Committee (as the result of the investigation) should recommend any change in the mode of management of the permanent way of the railways of the United Kingdom.

Breaking Load of Steel Rails.

At five feet bearings the breaking load of steel rails in pounds may be taken at 1,000 × weight of rail per yard in pounds.

Chemical analyses of average Bessemer rail steel, as made at present for heavy rails, run about as follows:—

	Per cent.		Per cent.		Per cent.
Carbon	·50	Sulphur	·08	Manganese	1·00
Phosphorus	·10	Silicon	·12	Iron	98·20

(*F. E. Abbott.*)

Cross-Overs.

Shortly after the Central London Railway was opened practically all the cross-overs on it were changed to manganese steel. They have been in use for over ten years, and there has been no necessity for renewing them. With ordinary steel the life, with the traffic which the Central London carries, would be only from three to six months. Taking the relative prices of ordinary steel and manganese steel cross-overs, the life of the latter in order to produce the same economy would require to be from three to four years. It is thus seen that manganese steel, which has already had a life of ten years, is by far the cheapest in the end, and obviates the trouble of continual renewal work.

Ballast.

Cubic Yards per Mile of Ballast.

Depth of Ballast in Inches.	Side Slope of Ballast, 1 to 1. Width in Feet.					
	Single Track.			Double Track.		
	10	11	12	21	22	23
12	2,151	2,347	2,543	3,303	4,499	4,694
18	3,373	3.667	3,961	6,601	6,895	7,188
24	4,700	5 085	5,477	8,997	9,389	9,780
30	6,111	6,601	7,090	11,491	11,980	12,469

The depth of the ballast should be 2 feet below the top of the rails—that is, 1 foot 7 inches in thickness above the formation level. The ballast is usually laid in a double thickness, the upper layer consisting of stones not exceeding 3 cubic inches in bulk, and averaging about 2 cubic inches. The lower layer may be of stones varying in size from 3 to 30 cubic inches in bulk.

The width of the top ballast beyond the cross-sleepers should be about 18 inches, the total width in the case of a single line of rails being 12 feet; in the case of a double line, 23 feet; in the case of a triple line, 34 feet; and for a quadruple line 45 feet. Slope of ballast at sides, 1 to 1.

Cost of Railway Construction.

In England, taking a fairly representative section of one of the main lines, outside the Metropolis, and constructed in recent years, as an example, the percentages of the cost of about 40,000*l.* per mile, work out somewhat as follows:—

	Per Cent.		Per Cent.
Land and compensation	10	Sidings	3
Fencing	1½	Junctions and signals	1
Earthworks	24	Stations, including buildings (roadside only)	6½
Tunnels	12	Contingencies, including parliamentary, administration, legal and engineering expenses	6
Viaducts	8	Maintenance	½
Bridges for roads	9		100
Accommodation works	2		
Culverts and drainage	5		
Permanent way, ballast, including main line	11½		

From this it will be seen that, for country lines, the value of land does not form so important a factor in the total cost as is generally understood. The necessity for very easy gradients, and flat curves, in order to admit of high speeds, involves heavy earthworks, viaducts and tunnels, and expensive, well-ballasted permanent way, whilst stations and sidings have to be extensive to accommodate the traffic.

Experience has shown how to adapt the design of railways to their special surroundings. Their cost has varied from about 630,000*l.* per mile in London, and from an average of 52,378*l.* per mile in the United Kingdom, and of 8,127*l.* per mile in India, to a cost, in some parts of South Africa and South America, of 3,200*l.* to 3,500*l.* per mile, or, with equipment, of 4,000*l.* per mile—a rate at which, in new countries and under fairly normal conditions, railways can be provided, suitable for a speed of 30 miles per hour, and for heavy trains. (*Sir Douglas Fox.*)

Table showing Gauges of Various Railways.

Details of Permanent Way.

Clear space outside rail, 4 ft. Middle space between two sets of rails, 6 ft. Clear space outside rail, 4 ft. Least head for the top of ballast, and least width for archways and tunnels, 13 ft. 1½ in. for single lines ; 24 ft. 3 ins. for double lines. Spaces required for slopes of ballast and benches beyond them on top of embankments, from 3 ft. 10½ ins. to 8 ft. 10½ ins. for single lines ; and from 3 ft. 9 ins. to 8 ft. 9 ins. for double lines. Total breadth on top of embankments, from 17 ft. to 22 ft. for single lines ; and from 28 ft. to 33 ft. for double lines.

Bridges.

Over-Bridges carrying roads over the railway are usually of the following spans : Over single line, 16 ft. to 18 ft. ; over double line, 28 ft. to 30 ft.

Widths of over-bridges, between inside of parapets, are regulated by Act of Parliament as

follows, the roads being of the widths given for 50 yards each way: Turnpike roads, 35 ft.; other public carriage roads, 25 ft.; turnpike roads, 30 ft.; other public carriage roads, 20 ft.; private roads, 12 ft.

Under-Bridges, carrying roads under railway. Span and head-room fixed by Act of Parliament: Turnpike road, clear head-room, 12 ft. at springing, 16 ft. for centre 12 ft. of arch; other public carriage road, clear head-room, 12 ft. at springing, 15 ft. for centre 13 ft. of arch; private road, clear head-room, 14 ft. for centre breadth of 9 ft. of arch.

Allowance for Impact in Bridges.

S = span in ft.; V = velocity in ft. per sec.; T = time in secs. required by a train travelling at velocity V to travel from the point where a given member commences to receive the stress, to the point where the stress is a maximum (i.e. in a plain girder, T is the time taken to pass half the span); D = maximum allowable deflection; t = time taken for a free falling body to fall through a height $D \therefore t^2 = \frac{D}{16}$, or $t = \frac{1}{4}\sqrt{D}$; P = percentage allowance for impact, then $P = \frac{50V\sqrt{D}}{S}$. As formula is correct for a single concentrated load only, it gives excessive allowances for long spans, and P may be reduced $\frac{1}{30}$th of its found value for each 25 ft. span in spans of over 25 ft. In all cases where V is such that the load traverses the half span in less time than t, the percentage for impact must be 100, the maximum V being fixed at 100 ft. per sec. For a deflection of $\frac{1}{2500}$ of the span, $P = \frac{V}{\sqrt{S}}$ less the allowance for spans above 25 ft.
